# Chapter 0:

## Manuel's notes

### Warning

These are unofficial lecture notes written by a student. They are messy, will almost surely contain errors, typos and misunderstandings and may not be kept up to date! I do however try my best and use these notes to prepare for my exams. Feel free to email me any corrections to [mh@mssh.dev](mailto:mh@mssh.dev) or [s6mlhinz@uni-bonn.de](mailto:s6mlhinz@uni-bonn.de).  
Happy learning!

Many thanks to Vincent for his feedback and some corrections!

### General Information

- Basis: [Basis](#)
- Website: <https://ins.uni-bonn.de/teachings/ss-2025-467-v5e1-advanced-topics/>
- Time slot(s): **Tuesday: 14-16** SR 2.035 and **Thursdays: 16-18** SR 2.035
- Exams: ?
- Deadlines: No exercise sheets / tutorials

## 0.1 Organization

- Focused on ingredients, won't get to the current state of the art
- Some algorithmic / numerical background (Euler method is fine)
- Control Problems (Steering the bike / car)

Start of lecture 01  
(10.4.2025)

The main source for this course is [2]. We will follow this somewhat closely, especially in the first part of the course!

---

# Chapter 1:

## Introduction to optimal control

1.  $u$  is the control (input / action)
2.  $y$  observations (outputs)
3.  $\phi : Y \rightarrow U$  policy
4. ff feed forward control (plan we had)

Interactions with the outside world might be hidden in the observations. Typically ff is in regard to some reference state. There might be some disturbances (holes in the road, ...).

The overall aim is to find a policy  $\phi$  that sticks close to  $r(k), k \geq 0$ .

$t$  is continuous,  $k$  is step  
by step / iterative

$$u(k) = u_{\text{ff}}(k) + U_{\text{fb}}(k)$$

where  $u_{\text{ff}}$  is the planing to reach the overall goal and  $u_{\text{fb}}$  actual steering, updated "all the time".  
Some examples from the book:

Figure 1.1: Sketch 1.01

Figure 1.2: Sketch 1.02: Mountain car

Difference: In Reinforcement learning, we don't start with a model / ode.  
Some part of reinforcement learning works model-free (i.e. assumes the model only implicitly)

Figure 1.3: Sketch 1.03: cart pole / inverted pendulum

Next example: Acrobot (more than one equilibrium)

## 1.1 State Space Models

We have some

- state space  $X, x \in X$
- action space  $U, u \in U$
- action at step  $k : u(k) \in U(k)$ , i.e. we might have some constraints

- observation space  $Y, y \in Y$

**Definition 1.** Given state, action and observation spaces  $X, U, Y$ , a state space model is defined by

$$x(k+1) = \mathcal{F}(x(k), u(k)) \quad (1)$$

$$y(k) = \mathcal{C}(x(k), u(k)) \quad (2)$$

$x(k)$  might include the past, might be useful for the stock trading problem

**Remark.** Overcomplicating problems by loading lots of information into the state space, might make the problem harder!

## 1.2 Linear State Space Model

$$x(k+1) = Fx(k) + Gu(k) \quad (3)$$

$$y(k) = Cx(k) + Du(k) \quad (4)$$

**Remark.** The representations (in terms of the matrices) might not be unique!

Common scenario for (3) is to keep  $x(k)$  near the origin. You have to think about robustness of the system. Disturbances should be handled by the system.

$$u(k) = -Kx(k).$$

Consider a disturbance under the same control:

$$u(k) = -Kx(k) + v(k)$$

inserting this into (3) yields

$$x(k+1) = (F - GK)x(k) - Gv(k)$$

$$y(k) = (C - DK)x(k) + Dv(k)$$

Closed vs open loop: In closed loops we don't change our course based on observations, while in open loop systems we do.

## 1.3 State Space Models in continuous Time

$$\frac{d}{dt}x = f(x, u)$$

for  $x \in \mathbb{R}^n, u \in \mathbb{R}^m$ . We often write  $u_t, x_t$  for  $u, x$  at time  $t$ . If  $f$  is linear we get

$$\frac{d}{dt}x = Ax + Bu$$

$$y = Cx + Du$$

Figure 1.4: Sketch 1.04

To discretize we use the forward Euler method. Given time interval  $\Delta$

$$x(k+1) = x(k) + \Delta f(x(k), u(k))$$

so in (1)  $\mathcal{F}(x, u) = x + \Delta f(x, u)$ . Using Taylor

$$x_{t+\Delta} = x_t \Delta f(x, u) + O(\Delta^2)$$

For the linear model we get  $F = I + \Delta A$

$$x(k+1) = x(k) + \Delta A x(k) + \underbrace{\Delta B}_{=:G} u(k)$$

For now fix some policy  $\phi$ , so  $u(k) = \phi(x(k))$ :

$$x(k+1) = \mathcal{F}(x(k))$$

**Assumption 2.** The state space  $X$  is equal to  $\mathbb{R}^n$  or a closed subset of  $\mathbb{R}^n$ .

**Definition 3.** An equilibrium  $x^e$  is a state at which is system is frozen:

$$x^e = \mathcal{F}(x^e).$$

**Definition 4.** Given a cost function  $C : X \rightarrow \mathbb{R}_+$  and a policy  $\phi$  we define

$$J_\phi(x) = J(x) = \sum_{k=0}^{\infty} C(x(k)), \quad x(0) = x$$

This is called total cost or value function of the policy  $\phi$ .

Given  $x^e$ , we usually assume  $C(x^e) = 0$ . Generally, we consider a discount factor  $\gamma^k$  in front of  $C(x(k))$ .

**Definition 5.** Denote by  $\mathcal{X}(k; x_0)$  the state step  $k$  with initial condition  $x_0$  and following fixed policy  $\phi$ . The equilibrium  $x^e$  is stable in the sense of Lyapunov if for all  $\epsilon > 0 \exists \delta > 0$  s.t.  $\|x_0 - x^e\| < \delta$ , then

$$\|\mathcal{X}(k; x_0) - \mathcal{X}(k; x^e)\| < \epsilon \forall k \geq 0$$

The same concept with a different sign comes up in RL under the term reward

Figure 1.5: Sketch about Lyapunov stability

**Definition 6.** An equilibrium is said to be **asymptotically stable** if  $x^e$  is stable in the sense of Lyapunov and for some  $\delta_0 > 0$ , whenever  $\|x_0 - x^e\| < \delta_0$ , it follows

$$\lim_{k \rightarrow \infty} \mathcal{X}(k, x_0) = x^e.$$

The set of  $x_0$  for which this holds is the **region of attraction** for  $x^e$ . An equilibrium is **globally asymptotically stable** if the region of attraction is  $X$ .

**Definition 7** (Lyapunov function). A function  $V : X \rightarrow \mathbb{R}_+$  is called **Lyapunov function**. We frequently assume  $V$  is **inf-compact**, i.e.: it holds

$$\forall x^0 \in X : \{x \in X \mid V(x) \leq V(x^0)\} \text{ is a bounded set.}$$

**Remark.** There is some variability in the definition of Lyapunov functions! We often assume  $V(x)$  is large if  $x$  is large.

**Sublevel sets:**

$$S_V(r) = \{x \in X \mid V(x) \leq r\}.$$

One can see with  $V$  being inf-compact  $S_V(r)$  is either

- empty
- the whole domain  $X$
- a bounded subset of  $X$ .

We usually want to avoid this

Usually,  $S_V(r) = X$  is impossible, a common assumption is **coersiveness**:

$$\lim_{\|x\| \rightarrow \infty} V(x) = \infty.$$

**Example.** •  $V(x) = x^2$ , coercive

- $V(x) = \frac{x^2}{(1+x)^2}$ , not coercive, but inf-compact  $r > 1 : S_V(r) = \mathbb{R}$ ,  $r < 1 : S_V(r) = [-a, a]$  with  $a = \sqrt{\frac{r}{1+r}}$
- $V(x) = e^x$  is neither

**Lemma 8.** Suppose that the cost function  $C$  and the value function  $J$  from definition 5 are non-negative and finite valued.

this is a assumption on the value function

1.  $J(x(k))$  is non-increasing in  $k$  and  $\lim_{k \rightarrow \infty} J(x(k)) = 0$  for each initial condition.
2. In addition let  $J$  be continuous, inf-compact and vanishing only at  $x^e$ . Then for each initial condition

$$\lim_{k \rightarrow \infty} x(k) = x^e$$

*Proof.* Consider  $J(x) = \sum_{k=0}^{\infty} c(x(k))$ , then

$$\begin{aligned} J(x) &= c(x) + \sum_{k=1}^{\infty} c(x(k)) \\ &= c(x) + \sum_{k=0}^{\infty} c(x^+(k)); \quad x^+(0) = \mathcal{F}(x) \\ &= c(x) + J(\mathcal{F}(x)) \end{aligned}$$

This is the **dynamic programming principle** for a **fixed policy**. It is also called **Bellmann equation**. For 1. from this it follows

$$J(x(k+1)) + c(x) - J(x(k)) = 0$$

summing up from  $k = 0$  up to  $N - 1$

$$\begin{aligned} J(x) &= J(x(N)) + \sum_{k=0}^{N-1} c(x(k)) \\ &\implies \text{non-increasing} \end{aligned}$$

We are separating one step!

This is the same Bellman from the curse of dimensionality!

Taking the limit

$$= \lim_{N \rightarrow \infty} \left[ J(x(N)) + \sum_{k=0}^{N-1} c(x(k)) \right] = \left[ \lim_{N \rightarrow \infty} J(x(N)) \right] + J(x)$$

using  $J(x)$  is finite gives (i).

For 2. with  $r = J(x)$ , we get  $x(k) \in S_J(r) \forall k$ . Now suppose  $\{x(k_i)\}$  is a convergent subsequence of the trajectory with limit  $x^\infty$ . Then  $J(x^\infty) = \lim_{i \rightarrow \infty} J(x(k_i)) = 0$  by the continuity of  $J$ . We assumed  $J(x) = 0 \iff x^e = x \implies x^\infty = x^e$ . Finally, the assumption follows, since each convergent subsequence reach the same value  $x^e$ .

□

**Definition 9** (Poisson's inequality). Let  $V, c : X \rightarrow \mathbb{R}_+$  and  $\eta \geq 0$ . Then **Poisson's inequality** states that

We often assume  $\eta = 0$

$$V(\mathcal{F}(x)) \leq V(x) - c(x) + \eta.$$

**Proposition 10.** Suppose the Poisson inequality holds with  $\eta = 0$ . Additionally  $V$  shall be continuous, inf-compact and it shall have a unique minima at  $x^e$ . Then  $x^e$  is stable in the sense of Lyapunov (**sitsoL**).

*Proof.*

$$\bigcap \{S_V(r) \mid r > V(x^e)\} = \{S_V(r)|_{r=V(x^e)}\}^{\text{unique minimizer}} \{x^e\}.$$

Using compactness we get: For each  $\epsilon > 0$ , we can find some  $r > V(x^e)$  and some  $\delta < \epsilon$  s.t.

$$\{x \in X \mid \|x - x^e\| < \delta\} \subset S_V(r) \subset \{x \in X \mid \|x - x^e\| < \epsilon\}$$

If  $\|x_0 - x^e\| < \delta$ , then  $x_0 \in S_V(r)$  and hence  $x(k) \in S_V(r)$  since  $V(x(k))$  is non-increasing. With the second inclusion we see

$$\|x(k) - x^e\| < \epsilon \forall k$$

This gives sitsoL.

□

**Proposition 11** (Comparison theorem). *Poisson's inequality implies*

1. For each  $N \geq 1$  and  $x = x(0)$

$$V(x(N)) + \sum_{k=0}^{N-1} c(x(k)) \leq V(x) + N\eta$$

2. If  $\eta = 0$ , then  $J(x) \leq V(x) \forall x$

3. Assume  $\eta = 0$  and  $V, c$  are continuous. Suppose that  $c$  is inf-compact and vanishes only at the equilibrium  $x^e$ . Then  $x^e$  is globally asymptotically stable.

*We don't write that explicitly, but we don't start in  $x^e$ !*

*Proof.* 1.

$$V(x(k+1)) - V(x(k)) + c(x(k)) \leq \eta$$

summing up from 0 to  $N-1$ :

$$V(x(N)) - V(x(0)) + \sum_{k=0}^{N-1} c(x(k)) \leq N\eta$$

2. for  $\eta = 0$  the above is  $\leq 0$ , so  $\sum_{k=0}^{N-1} c(x(k)) \leq V(x(0)) - V(x(N)) \leq V(x(0))$  where the LHS converges to  $J(x(0))$  for  $N \rightarrow \infty$

3. Show sitsoL, with  $\eta = 0$  it follows from definition 9 that  $V(x) \geq c(x)$ , which gives  $V$  is also inf-compact.  $c$  is vanishing only at  $x^e$ , so  $V(x(k))$  is strictly decreasing. When  $x(k) \neq x^e$ , implies  $V(x(k)) \downarrow V(x^e)$  for each  $x(0)$ . Further

This is important!

$$V(x^e) < V(x(0)) \quad \forall x(0) \in X \setminus \{x^e\}.$$

So it is a unique minimum.  $V$  has therefore the properties of proposition 10, which gives sitsoL. For global: with 1. we get

$$\lim_{k \rightarrow \infty} c(x(k)) = 0$$

and assumptions give us by lemma 8 that  $x(k) \rightarrow x^e$  as  $k \rightarrow \infty$ . So, we converge from any initial condition, which gives global asymptotical stability.  $\square$

**Proposition 12.** *Suppose that  $V(\mathcal{F}(x)) = V(x) - c(x)$ . Further, we assume that*

1.  $J$  is continuous, inf-compact, vanishing only at  $x^e$

2.  $V$  is continuous

*Then  $J(x) = V(x) - V(x^e)$ .*

*Proof.* As before we sum up:

$$V(x(N)) + \underbrace{\sum_{k=0}^{N-1} c(x(k))}_{J(x(N-1)) \xrightarrow{N \rightarrow \infty} J(x)} = V(x).$$

Lemma 8 together with the continuity of  $V$  implies that

$$V(x(N)) \rightarrow V(x^e) \quad \text{as } N \rightarrow \infty.$$

This gives

$$V(x^e) + J(x) = V(x)$$

$\square$

Start of lecture 03  
(17.04.2025)

**Example** (Linear state space model). Setting  $x(k+1) = \mathcal{F}(x(k))$ , now with linear dynamics:

$$x(k+1) = Fx(k) = F^{k+1}x(0) = F^{k+1}x.$$

Assume quadratic cost  $c(x) = x^\top Sx$ , where  $S$  is symmetric and positive definite. Observe

$$c(x(k)) = (F^k x)^\top S F^k x$$

Summing up yields

$$J(x) = x^\top \underbrace{\left[ \sum_{k=0}^{\infty} (F^k)^\top S F^k \right]}_{=:M} x$$

This satisfies a linear fixed point equation:

$$M = S + F^\top M F \quad (5)$$

This is also called  
discrete time  
Lyapunov equation

One can show for the linear state space model, that the following are equivalent:

1. the origin is asymptotically stable
2. the origin is globally asymptotically stable
3. Each eigenvalue  $\lambda$  of  $F$  satisfies  $|\lambda| < 1$
4. (5) admits a solution  $M$  positive semi-definite for any  $S$  positive semidefinite.

Reference: [1]

Consider 1 without  $y$

$$y(k+1) = \mathcal{F}(x(k), u(k))$$

with

$$c : X \times U \rightarrow \mathbb{R}_+.$$

The total cost  $J_\phi$  for a given  $\phi$  given  $u(k) = \phi(x(k))$  is

$$J_\phi(x) = \sum_{k=0}^{\infty} c(x(k), u(k)).$$

The optimal value function is the minimum over all controls

$$J^*(x) = \min_{\underline{U}=[u(0), u(1), \dots]} \sum_{k=0}^{\infty} c(x(k), u(k)), \quad x(0) = x \in X \quad (6)$$

This describes the  
optimal control policy  
(OCP)

**Remark.** The minimizer might not be unique! In harder settings this might need to be an inf!

**Goal:** Find a control sequence that achieves the minimum.

Computationally we can't expect to calculate  $J_\phi$  exactly, but we will approximate it.

and the corresponding  
policy

**Remark.** We are in the infinite horizon setting (infinite time steps) to talk about the stability. For this it is important that the equilibrium has cost 0. Without an equilibrium we can also think about discounted value functions

$$J_\phi = \sum_{k=0}^{\infty} \gamma^k c(x(k), u(k))$$

We will see later that it holds for the sequence  $x^*$  achieving the minimum

$$J^*(x^*(k)) = c(x^*(k), u^*(k)) + J^*(x^*(k+1))$$

which is definition 9 with  $\eta = 0$  and equality.

Proposition 11 implies, under some conditions, that  $x^e$  is globally asymptotically stable.

Under the following assumptions  $J^*$  is finite:

1. there is a (target) state  $x^e$  that is an equilibria for some control  $F(x^e, u^e) = x^e$
2.  $c \geq 0, c(x^e, u^e) = 0$
3. for any initial condition  $x(0) = x$  there is a control sequence  $\underline{u}$  and a time  $T$ , such that  $x(T) = x^e$  for  $x(0) = x$  using control  $\underline{u}$ .

This is sometimes called controllability

**Example** (Linear Quadratic Regulator). Consider linear dynamics 3 from the first lecture with quadratic cost  $c(x, u) = x^\top Sx + u^\top Ru$  with  $S$  positive semi-definite and  $R$  positive definite.

Reminder:  $u = -Kx$ .

If there is a policy for which  $J^*$  is finite, then

$$J^*(x) = x^\top M^* x$$

with  $M^*$  positive semi-definite and

$$\phi^*(x) = -K^*(x)$$

with  $K^*$  depends on  $M^*, R, F, G$ .

and implicitly on  $c$

## Bellmann equation

Figure 1.6: Sketch 1.06; Principle of optimality

### Observation:

$$\begin{aligned}
 J^*(x) &= \min_{\underline{u}} \left[ \sum_{k=0}^{k_m-1} c(x(k), u(k)) + \sum_{k_m}^{\infty} c(x(k), u(k)) \right] \\
 &= \min_{u[0, \dots, k_m-1]} \left[ \sum_{k=0}^{k_m-1} c(x(k), u(k)) + \underbrace{\min_{u[k_m, \dots]} \sum_{k_m}^{\infty} c(x(k), u(k))}_{=J^*(x(k_m))} \right]
 \end{aligned}$$

This gives

$$J^*(x) = \min_{u[0, \dots, k_m-1]} \left[ \sum_{k=0}^{k_m-1} c(x(k), u(k)) \right] + J^*(x(k_m)).$$

which can be seen as a kind of fix point equation

With  $k_m = 1$  we have shown the following theorem

**Theorem 13** (Bellmann equation, Dynamic Programming equation). Assume that  $J^*$  is finite and optimal control  $u^*$  solving (6) exists. Then the value function satisfies

$$J^*(x) = \min_u \{c(x, u) + J^*(\mathcal{F}(x, u))\} \quad (7)$$

Suppose the minimum is unique for each  $x$  and let  $\phi^*(x)$  denote the minimum feedback law at  $x$ . Then the optimal control is expressed as

$$u^*(k) = \phi^*(x^*(k)).$$

**Definition 14** (Q-function). The function of two variables within the minimum in (7) is called Q-function.

$$Q^*(x, u) = c(x, u) + J^*(\mathcal{F}(x, u))$$

In the optimal case we write  $Q^*$ . Thus

$$J^*(x) = \min_{\bar{u}} Q^*(x, \bar{u}).$$

The optimal feedback law is then

$$\phi^*(x) \in \operatorname{argmin}_u Q^*(x, u).$$

*Definition, which is not so useful for the analysis, but for the practical application!*

The Q-function solves the fixed point equation

$$Q^*(x, u) = c(x, u) + \min_u Q^*(\mathcal{F}(x, u), u).$$

This already gives a hint for an algorithm coming later next lecture.

**Remark.** In RL the difference is that we don't know the model, we only observe state action pairs. This motivates the Q-function.

## Some concepts from Reinforcement Learning

### Actors and critic:

Given is a parameterized family of policies  $\{\phi^\theta \mid \theta \in \mathbb{R}^d\}$ . the actors. For each  $\theta$ , observe the trajectories by their states  $x$  and actions  $u$  determined by their policy.

The critic approximates the associated value function  $\tilde{J}_\theta$ . Aim for the minimum

$$\theta^* = \operatorname{argmin}_\theta \langle v, \tilde{J}_\theta \rangle,$$

where the weight vector  $v \geq 0$  reflects the weighting of the states.  $v(x)$  is large for *important* states.

scalar product in  $\mathbb{R}^n$  (all states?)

### Temporal differences:

$$J_\theta(x(k)) = c(x(k), u(k \mid \theta)) + J_\theta(x(k+1))$$

Look for an approximation  $\hat{J}$  for which the error is small (w.r.t. the equality above).

Temporal differences are

$$D_{k+1}(\hat{J}) := -\hat{J}(x(k)) + \hat{J}(x(k+1)) + c(x(k), u(k)).$$

What changes, or what is the information gain

After  $N$  samples

$$\Gamma(\hat{J}) := \frac{1}{N} \sum_{k=0}^{N-1} D_{k+1}(\hat{J})^2.$$

We can optimize / minimize this.

There is a whole class of TD algorithms and those fit into the actors critic approach!

Start of lecture 04  
(22.04.2025)

## 1.4 Value iteration

We approximate  $J^*$  by a sequence of  $V^k$  given an initial value function  $V^0$ .

$$V^{k+1}(x) = \min_u \{c(x, u) + V^k(\mathcal{F}(x, u))\}, x \in X, k \geq 0$$

This is called **value iteration** often shortened to VI.

For infinite state spaces we will have to fix this algorithm for memory related reasons

### Algorithm 1 Value iteration

**Input:** Start with an initial value function  $V^0$

**Output:** Estimates  $V^{k+1}$

$n = 0$

**while** not good enough **do**

Value function improvement to obtain next value function

$$V^{k+1}(x) = \min_u \{c(x, u) + V^k(\mathcal{F}(x, u))\}, x \in X, k \geq 0$$

**end while**

**Proposition 15.** Let  $V^0$  be chosen with non-negative entries and  $V^0(x^e) = 0$ . Further, we assume

1.  $X, U$  are finite sets
2.  $c$  is non-negative and vanishes only at  $(x^e, u^e)$ , and  $J^*$  is finite valued.

Then there is  $n_0 \geq 1$  such that

$$V^k(x) = J^*(x), x \in X, k \geq n_0.$$

*Proof.* Let  $\phi^*(x)$  be an optimal policy, and let  $n_0 \geq 1$  denote the value such that

$$(x^*(k), u^*(k)) = (x^e, u^e)$$

for  $k \geq n_0$ . This exists since  $J^*$  is finite.

Using the principle of optimality (6) we can show

$$V^n(x) = \min_{u[0, \dots, n-1]} \left\{ \sum_{k=0}^{n-1} c(x(k), u(k)) + V^0(x(n)) \right\}, x(0) \in X \quad (8)$$

This gives

$$V^n(x) \leq \sum_{k=0}^{n-1} c(x(k), u(k)) + V^0(x(n)) \text{ for all } u \text{ including } u(k) = \phi^*(k)$$

$$\stackrel{n \geq n_0}{=} J^*(x) + V^0(x^e) = J^*(x)$$

For such  $n$ , the inequality must be an equality, due to (8) and the use of the optimal policy.  $\square$

VI provides a sequence of policies  $\phi^n$

$$\phi^n(x) \in \operatorname{argmin}_u \{c(x, u) + V^n(\mathcal{F}(x, u))\}.$$

If we assume that  $V^0$  is non-negative and satisfies poisson's inequality(9) for some  $\eta \geq 0$

$$V^0(\mathcal{F}(x, u)) \leq V^0(x) - c(x, \phi^0(x)) + \eta, x \in X$$

then we get the following statement

We really exploit the finiteness!

**Proposition 16.** Suppose that  $V^0$  is non-negative and it holds

$$\begin{aligned} \min_u (c(x, u) + V^0(\mathcal{F}(x, u))) &= \{c(x, u) + V^0(\mathcal{F}(x, u))\} |_{u=\phi^0(x)} \\ &\leq V^0(x) + \eta, \quad x \in X \end{aligned}$$

Then a corresponding bound holds for each  $n$

$$\{c(x, u) + V^n(\mathcal{F}(x, u))\} |_{u=\phi^0(x)} \leq V^n(x) + \eta_n, \quad x \in X,$$

where  $\eta_i$  is non-increasing:

$$\eta \geq \eta_0 \geq \eta_1 \dots$$

*Proof.* Write  $B^n(x) = V^{n+1}(x) - V^n(x)$

$$\eta_n := \sup_x B^n(x).$$

This is (connected to?)  
the Bellman error

Value iteration gives

$$\begin{aligned} \{c(x, u) + V^n(\mathcal{F}(x, u))\} |_{u=\phi^n(x)} &= \min_u \{c(x, u) + V^n(\mathcal{F}(x, u))\} \\ &= V^{n+1}(x) = V^n(x) + B^n(x) \\ &\leq V^n(x) + \eta_n \end{aligned}$$

To show that the  $\eta$  are non-increasing, we consider

$$V^1(x) = \{c(x, u) + V^0(\mathcal{F}(x, u))\} |_{u=\phi^0(x)} \stackrel{\text{Assumption}}{\leq} V^0(x) + \eta$$

which gives  $B^0(x) \leq \eta \forall x \implies \eta_0 \leq \eta$ .

For  $n \geq 1$  The trick is using the old control in the second line:

$$\begin{aligned} V^n(x) &= \{c(x, u) + V^{n-1}(\mathcal{F}(x, u))\} |_{u=\phi^{n-1}(x)} \\ V^{n+1}(x) &\leq \{c(x, u) + V^n(\mathcal{F}(x, u))\} |_{u=\phi^{n-1}(x)} \end{aligned}$$

So,

$$V^{n+1}(x) - V^n(x) \leq \{V^n(\mathcal{F}(x, u)) - V^{n-1}(\mathcal{F}(x, u))\} |_{u=\phi^{n-1}(x)} \leq \eta_{n-1}.$$

Hence,  $\eta_n = \sup_x B^n(x) \leq \eta_{n-1}$ . □

Now consider  $\eta = 0$ , so for each  $n$

$$\{c(x, u) + V^n(\mathcal{F}(x, u))\} |_{u=\phi^n(x)} \leq V^n(x)$$

with proposition 11 it follows

$$J^* \leq V^n(x), \quad x \in X,$$

where  $J^*$  is the total cost using policy  $\phi^n$ .

One view of policy iteration is the focus on updating the policy function!

## 1.5 Policy iteration

Start with an initial policy  $\phi^0, n = 0$

- Compute the total cost for the policy  $\phi^n$ , this is called policy evaluation

$$J^n(x) = \sum_{k=0}^{\infty} c(x(k), u(k)), \quad u(k) = \phi^n(x(k)) \forall x \in X$$

- perform policy improvement to obtain the next policy

$$\phi^{n+1}(x) \in \operatorname{argmin}_u \{c(x, u) + J^n(\mathcal{F}(x, u))\}, \quad x \in X$$

- while *not good enough*

This is sometimes also called Howard's algorithm.

**Remark.** The first step is some linearization and the second is the update. Like a generalization of Newton's method

**Algorithm 2** Policy iteration

**Input:** Start with an initial policy  $\phi^0$

**Output:** Estimates  $J^n(x), \phi^{n+1}(x)$

$n = 0$

**while** not good enough **do**

    Compute the total cost for the policy  $\phi^n$ , this is called policy evaluation

$$J^n(x) = \sum_{k=0}^{\infty} c(x(k), u(k)), \quad u(k) = \phi^n(x(k)) \quad \forall x \in X$$

    perform **policy improvement** to obtain the next policy

$$\phi^{n+1}(x) \in \operatorname{argmin}_u \{c(x, u) + J^n(\mathcal{F}(x, u))\}, \quad x \in X$$

**end while**

**Proposition 17.** Suppose that  $J^0$  for  $\phi^0$  is finite valued. Then for each  $n \geq 0$

$$\{c(x, u) + J^n(\mathcal{F}(x, u))\}_{|_{u=\phi^{n+1}(x)}} \leq J^n(x), \quad x \in X$$

and consequently, the value functions are non-increasing

$$J^0(x) \geq J^1(x) \geq \dots$$

*Proof.* Similar to the proof of proposition 16, where the non-increasing sequence again follows from proposition 11.  $\square$

Here we always assumed that we can compute everything, especially  $\mathcal{F}$  and the infinite sum.

## 1.6 Exploration

In RL we learn from observations, each state-action pair, new state and observed cost gives us information. We need *good* and *useful* information.

Consider a policy that is not optimal, but has  $x(k) \rightarrow x^e$  reasonably rapidly, where we assume  $c(x^e, \cdot) = 0$ . Typically we have continuity

$$\begin{aligned} \lim_{k \rightarrow \infty} D_{k+1}(\hat{J}) &= \lim_{k \rightarrow \infty} \left[ -\hat{J}(x(k)) + \hat{J}(x(k+1)) + c(x(k), u(k)) \right] \\ &= -\hat{J}(x^e) + \hat{J}(x^e) + 0 = 0. \end{aligned}$$

This is not much information, one cannot further improve the policy!

$$\Gamma^\epsilon(\hat{J}, x^i) = \frac{1}{N_\epsilon} \sum_{k=0}^{N_\epsilon-1} [D_{k+1}(\hat{J})]^2, \quad x(0) = x^i$$

To avoid getting *small* information from long trajectories, one can take a couple of shorter ones.

$$\hat{\Gamma}(\hat{J}) = \frac{1}{M} \sum_{i=1}^M \Gamma^\epsilon(\hat{J}; x^i)$$

How to choose  $x^i$  is current research. Much of the theoretical research assume that “every state is assumed regularly”, which is nice for results, but not so nice realistic in most applications.

Another way to get more diverse information is to use **exploration**. Namely one modifies the trajectories, not strictly follows  $\phi^n$ .

$u(k) = \hat{\phi}(x(k), \zeta(k))$ , where  $\zeta(k)$  is some form of noise. Typically

this is also sometimes called off-policy and on-policy

1.  $\hat{\phi}(x(k), \zeta(k)) = \phi^\theta(k)$  for most  $k$
2. Choose action to explore the state-action space (e.g. randomly) the other times

Generally, the trajectory to gather information stems from a different policy than the current estimate  $\phi^\theta$ . This dilemma is called the exploration-exploitation dilemma.

Start of lecture 05  
(24.04.2025)

## 1.7 Linear Quadratic Regulator, Revisited

We had  $J^*(x) = x^\top M^* x$  and quadratic costs,  $c(x, u) = x^\top S x + u^\top R u$ .  
For the  $Q$ -function:

$$Q^*(x, u) = c(x, u) + J^*(Fx + Gu).$$

An optimal policy  $\phi$  is a minimum over  $Q$  w.r.t.  $u$ :

$$0 = \nabla_u Q^*(x, u^*) = 2Ru^* + 2G^\top M^*(Fx + Gu^*)$$

Assuming  $R$  is positive definite; then  $R + G^\top M^* G$  is positive definite and therefore invertible.

$$K^* = [R + G^\top M^* G]^{-1} G^\top M^* F$$

and

$$\phi^*(x) = -Kx.$$

To obtain  $M^*$  we can solve a fixed point equation called the algebraic Riccati equation

This is a hint, we will  
prob. revisit this later

$$M^* = F^\top \left( M^* - M^* G [R + G^\top M^* G]^{-1} G^\top M^* F + S \right) \quad (9)$$

## 1.8 Approximate $Q$ -functions

Consider a family of  $Q$ -functions  $\{Q^\theta \mid \theta \in \mathbb{R}^d\}$  to approximate  $Q^*$ . Classically used is a linear parametrization

$$Q^\theta(x, u) = \theta^\top \psi(x, u), \quad \theta \in \mathbb{R}^d$$

where  $\psi_i : X \times U \rightarrow \mathbb{R}$ ,  $1 \leq i \leq d$  is some set of basis functions. Given  $Q^\theta$  we have  $\phi^\theta(x) \in \operatorname{argmin}_u Q^\theta(x, u)$ ,  $x \in X$ .

Think kernels, finite  
element basis,...

Policy iteration for  $Q$ -functions:

1. obtain  $\theta^n$  to get an approximation of  $Q^{\theta^n}$  where  
 $Q^{\theta^n}(x, u) = c(x, u) + Q^{\theta^n}(x^+, u^+)$ ,  $x^+ = \mathcal{F}(x, u)$ ,  $u^+ = \phi^n(x^+)$
2. define new policy  $\phi^{n+1}(x) := \phi^{\theta^n}$

Approximation since we  
do this sample-based in  
RL

As an alternative, consider dynamic programming equation from definition 14:

$$Q^*(x, u) = c(x, u) + \min_{\bar{u}} Q^*(\mathcal{F}(x, u), \bar{u}).$$

We follow a given/ observed state-action trajectory  $(x(k), u(k))_{k=0}^N$

$$Q^*(x(k), u(k)) = c(x(k), u(k)) + Q^*(x(k+1), u(k+1))$$

The temporal difference / Bellmann error

$$D_{k+1}(Q^\theta) = -Q^\theta(x(k), u(k)) + c(x(k), u(k)) + Q^\theta(x(k+1), u(k+1))$$

If  $Q^\theta = Q^*$  then  $D_{k+1}(Q^\theta) = 0 \forall k$ . In  $Q$ -learning algorithms, one chooses  $\theta^n$  such that  $D_{k+1}(Q^{\theta^n})$  is small in a suitable fashion. So we minimize  $\theta$  to achieve this, i.e.

$$\Gamma^\epsilon(\theta) = \frac{1}{N} \sum_{i=0}^{N-1} [D_{k+1}(Q^\theta)]^2$$

## 1.9 Bandits

Theory of multi-armed bandits. One has to accept some loss through exploration in order to achieve(find) the best strategy. One exploits the learned strategy when choosing an action according to it.

In the control of dynamic systems one has for each state  $x$  (or  $x(k)$ ) a multi-armed bandit.

## 1.10 Other control formulations

Discounted cost:

$$J^*(x) = \min_{\underline{u}} \sum_{k=0}^{\infty} \gamma^k c(x(k), u(k)), \quad x(0) \in X$$

where  $\gamma \in (0, 1)$  is the discount factor.

Shortest Path Problem: Given  $A \subset X$  define  $\tau_A := \min\{k \geq 1 \mid x(k) \in A\}$ .

$$J^*(x) = \min_u \sum_{k=0}^{\tau_A-1} \gamma^k c(x(k), u(k)), \quad x(0) = x.$$

This is problematic, since we might have longer path with lower cost ...

**Proposition 18.** *If  $J^*$  is finite valued, then it is the solution to the dynamic programming equation in the following sense:*

$$J^*(x) = \min_u \{c(x, u) + \gamma 1_{\{\mathcal{F}(x, u) \in A^c\}} J^*(\mathcal{F}(x, u))\}, \quad x \in X$$

where  $1_{\{\dots\}}$  denotes an indicator function.

*Proof.*

$$\begin{aligned} J^*(x) &= \min_{\underline{u}} \left\{ c(x, \underline{u}) + \sum_{k=1}^{\tau_A-1} \gamma^k c(x(k), u(k)) \right\} \\ \tau_A=1 &\implies \sum=0 \quad \min_{u(0)} \left\{ c(x, u(0)) + \gamma 1_{\{x(1) \in A^c\}} + \min_{u[1, \dots, \tau_A]} \left\{ \sum_{k=1}^{\tau_A-1} \gamma^{k-1} c(x(k), u(k)) \right\} \right\} \\ &= \min_{u(0)} \{c(x, u(0)) + \gamma 1_{\{x(1) \in A^c\}} J^*(x(1))\} \end{aligned}$$

$c(x, u(0))$  since we're extracting the first element of the sum

where  $x(1) = \mathcal{F}(x, u(0))$ . □

To formulate this as a discounted problem

1. modify the cost function  $c_A(x, u) = \begin{cases} c(x, u) & x \in A^c \\ 0 & x \in A \end{cases}$
2. modify the state dynamics  $\mathcal{F}_A(x, u) = \begin{cases} \mathcal{F}(x, u) & x \in A^c \\ x & x \in A \end{cases}$

Figure 1.7: Sketch: mountain car value function

Can be numerically very hard, since the value function can be quite discontinuous, but not all value functions are that bad.

**Finite Horizon** Fix horizon  $N \geq 1$  and define

$$J^*(x) = \min_{u[0,N]} \sum_{k=0}^N c(x(k), u(k)), \quad x(0) = x \in X.$$

We can connect to the optimal control problem by

1. enlarging the state space  $x^a(k) = (x(k), \tau(k))$ , where  $\tau(k) = \tau(0) + k$ ,  $k \geq 0$
2. modify the cost function  $c^a((x, \tau), u) = \begin{cases} c(x, u) & \tau \leq N \\ 0 & \tau > N \end{cases}$

Then

$$J^*(x^a) = \min_{\underline{u}} \underbrace{\sum_{k=0}^{\infty} c^a(x^a(k), u(k))}_{J^*(x, \tau)}, \quad x^a(0) = (x, 0)$$

The Bellmann equation from theorem 13 now becomes

$$J^*(x, \tau) = \min_u \{c(x, u)1_{\{\tau \leq N\}} + J^*(\mathcal{F}(x, u), \tau + 1)\} \quad (10)$$

For  $\tau > N$ , it follows that  $J^*(x, \tau) = 0$ . This gives

$$J^*(x, N) = \min_u c(x, u) = \bar{c}(x).$$

kind of a boundary condition

So,

$$J^*(x, N-1) = \min_u \{c(x, u) + \bar{c}(\mathcal{F}(x, u))\}$$

repeating this backwards in time yields

$$J^*(x, 0) = J^*(x^a).$$

For the policy  $\phi^*(x, \tau) \in \operatorname{argmin}_u \{c(x, u) + J^*(\mathcal{F}(x, u), \tau + 1)\}, \tau \leq N$  and

$$u^*(k) = \phi^*(x^*(k), k).$$

Start of lecture 06  
(29.04.2025)

### Model Predictive Control

Here, the policy is computed on-the-fly at each step of the state-action trajectory as a finite horizon problem. The control is

$$u(k) = \phi^{\text{mpc}}(x^*(k)) = \phi^*(x^*(k), 0),$$

where  $\phi^*$  from the finite horizon setting (10) for *small*  $N$ .

Consider

$$J^{\text{mpc}}(x) = \sum_{k=0}^{\infty} c(x(k), u(k)), \quad x(0) = x, u(k) = \phi^{\text{mpc}}(x(k)).$$

Due to the finite horizon  
we are not optimal ...

**Proposition 19.** Consider  $u(k)$  from above with

$$J^*(x; 0) = \min_{u[0, N-1]} \sum_{k=0}^{N-1} c(x(k), u(k)) + V^0(x(N)),$$

where  $V^0 : X \rightarrow \mathbb{R}^+$  satisfies the assumption from proposition 16 with  $\eta = 0$ :

$$\min_u \{c(x, u) + V^0(\mathcal{F}(x, u))\} \leq V^0(x).$$

Then the total cost  $J^{\text{mpc}}$  is finite everywhere.

*Proof.* Using an equation from proposition 15:

$$V^N(x) = \min_{u[0, N-1]} \left\{ \sum_{k=0}^{N-1} c(x(k), u(k)) + V^0(x(N)) \right\}$$

and the definition of  $J^*$  from above we get  $J^*(x, 0) = V^N(x)$  Proposition 16 then gives the bound

$$\{c(x, u) + V(\mathcal{F}(x, u))\}_{|u=\phi^{\text{mpc}}(x)} \leq V(x) = V^N(x)$$

This is also a version of a  
poisson inequality

From the Comparison theorem 11, it follows that  $J^{\text{mpc}}$  is finite.  $\square$

## 1.11 Geometry in continuous time

Consider  $x(k+1) = \mathcal{F}(x(k))$ , now in continuous time:

$$\frac{d}{dt}x_t = f(x_t) \text{ or } \frac{d}{dx}x = f(x)$$

$\mathcal{X}(t, x_0)$  is the solution to the differential equation above. Definition 5, 6 carry over.

$$\lim_{t \rightarrow \infty} \mathcal{X}(t, x_0) = x^e$$

**Definition 20.** A function  $V : X \rightarrow \mathbb{R}_0^+$  is called Lyapunov function for global asymptotic stability if the following conditions hold:

- (i)  $V \in C^1$
- (ii)  $V$  is inf-compact
- (iii) For any solution  $x$ , whenever  $X_t \neq x^e$

$$\frac{d}{dt}V(x_t) < 0.$$

If  $x_t = x^e$ , we have  $V(x_{t+s}) = V(x^e)$  for all  $s \geq 0$ , so  $\frac{d}{dt}V(x^e) = 0$ .

If we look back at the proof of proposition 10 and proposition 11 (iii), we can see that these also carry over to the continuous case. So we get

**Proposition 21** (Extension of prop 11 (iii)). *If there exists a Lyapunov function after definition V 20, then the equilibrium  $x^e$  is globally asymptotically stable.*

*Since we did not exploit the step-wise nature previously*

The continuous version of Poisson's inequality is then

$$\langle \nabla V(x), f(x) \rangle \leq -c(x) + \eta \quad (11)$$

using the chain rule we get

$$\frac{d}{dt}V(x) \leq -c(x) + \eta$$

further observing

$$0 \leq V(x_T) = V(x_0) + \int_0^T \frac{d}{dt}V(X_t)dt \leq V(x_0) + T\eta - \int_0^T c(x_t)dt$$

we have shown

**Proposition 22** (Continuous Comparison theorem). *If (11) holds for non-negative  $c, V, \eta$ , then we have*

$$V(X_t) + \int_0^T c(x_t)dt \leq V(x) + T\eta, \quad x_0 = x \in X, T > 0 \quad (12)$$

If  $\eta = 0$

$$\int_0^\infty c(x_t)dt \leq V(x)$$

the total cost is bounded.

## 1.12 Optimal control in continuous time

$$\frac{d}{dt}x = f(x, u)$$

with total cost for  $\underline{u} = u[0, \infty)$

$$J(\underline{u}) = \int_0^\infty c(x_t, u_t)dt.$$

As before, we minimize over  $u$  and want  $J$  to be finite. We assume

$$f(x^e, u^e) = 0$$

for some  $u^e$  and

$$c(x^e, u^e) = 0$$

which yields that  $J$  is finite. As before

$$J^*(x) = \min_u \int_0^\infty c(x_t, u_t)dt, \quad x_0 = x \in X.$$

We extend the Bellmann equation to continuous times

$$\begin{aligned} J^*(x) &= \min_{u[0, \infty]} \left[ \int_0^{t_m} c(x_t, u_t)dt + \int_{t_m}^\infty c(x_t, u_t)dt \right] \\ &= \min_{u[0, t_m]} \left[ \int_0^{t_m} c(x_t, u_t)dt + \underbrace{\min_{u[t_m, \infty)} \int_{t_m}^\infty c(x_t, u_t)dt}_{J^*(x_{t_m})} \right] \end{aligned}$$

Same principle of optimality: What happens for  $t_m \downarrow 0$ . We assume  $J^* \in C^1$  and write  $\Delta x = x_{t_m} - x_0 = x_m - x$ . We now use Taylor on the above expression

$$\begin{aligned} J^*(x) &= \min_{u[0, t_m]} \{c(x_t, u_t)t_m + J^*(x) + \nabla J^*(x) \cdot \Delta x + o(t_m)\} \\ \implies 0 &= \min_{u[0, t_m]} \left\{ \underbrace{c(x_t, u_t)}_{\rightarrow 0} \underbrace{\frac{t_m}{t_m}}_{\rightarrow 0} + \nabla J^*(x) \cdot \underbrace{\frac{\Delta x}{t_m}}_{\substack{\frac{d}{dt}|_{t=0} \\ = f(x_0, u_0)}} \right\} + \underbrace{o(1)}_{\rightarrow 0} \\ \implies 0 &= \min_u [c(x, u) + \nabla J^*(x) \cdot f(x_0, u_0)] \end{aligned}$$

this is a strong assumption! In principle we would need to talk about viscosity solutions ... Even weak solutions are not enough

**Theorem 23.** *If the value function  $J^*$  has continuous derivatives, then it satisfies the Hamilton-Jacobi-Bellmann equation*

$$0 = \min_u [c(x, u) + \nabla J^*(x) \cdot f(x_0, u_0)] \quad (13)$$

The term to minimize has an interpretation as an Hamiltonian

$$H(x, p, u) = c(x, u) + p^\top f(x, u).$$

One can show

**Theorem 24.** *Suppose that an optimal state-action pair exists and that  $J^* \in C^1$ . Then  $u_t^*$  must minimize for each  $t$*

$$\min_u H(x_t^*, p_t^*, u) = H(x_t^*, p_t^*, u_t^*)$$

with  $p_t^* = \nabla_x J^*(x_t^*)$ .

**Remark.** *Relaxing away from  $\nabla J^*$  or  $\nabla J$  can have theoretical and computational advantages.*

### 1.13 Linear quadratic regulator revisited (once more)

$$\begin{aligned} \frac{d}{dt}x &= Fx + Gu, \quad x(0) = x_0 \\ c(x, u) &= x^\top Sx + u^\top Ru \end{aligned}$$

everything we observed so far carries over, assuming  $J^*$  is finite, we have

$$J^*(x) = x^\top M^* x$$

the HSB (13) gives

$$\begin{aligned} \phi^*(x) &= \operatorname{argmin}_u \{x^\top Sx + u^\top Ru + [2M^*x]^\top [Fx + Gu]\} \\ &= \operatorname{argmin}_u \{u^\top Ru + 2x^\top M^*Gu\} \end{aligned}$$

So,

$$0 = \nabla_u \{u^\top Ru + 2x^\top M^*Gu\}|_{u=\phi^*(x)}$$

and we get

$$\phi^*(x) = -R^{-1}G^\top M^*x$$

and

$$\frac{d}{dt}x^* = [F - GR^{-1}G^\top M^*]x^*.$$

HSB (13) further gives

$$\begin{aligned} 0 &= \{x^\top Sx + u^\top Ru + [2M^*x]^\top [Fx + Gu]\}|_{u=\phi^*(x)} \\ &= x^\top \{S + M^*GR^{-1}G^\top M^*\}x + x^\top \{2M^*F + 2M^*GR^{-1}G^\top M^*\}x \end{aligned}$$

using  $2x^\top M^* F x = x^\top [M^* F + F^\top M^*]$  we get

$$\begin{aligned} &= x^\top \{S + M^* F + F^\top M^* - M^* G R^{-1} G^\top M^*\} x \\ &\quad \{S + M^* F + F^\top M^* - M^* G R^{-1} G^\top M^*\} \end{aligned}$$

holds for any  $x$  and is symmetric, so it follows  $M^*$  is a positive definite solution to the algebraic Riccati equation

$$0 = S + M^* F + F^\top M^* - M^* G R^{-1} G^\top M^*$$

---

# Chapter 2:

## ODE methods for algorithm design

### 2.1 ODE methods for algorithm design

Start of lecture 07  
(06.05.2025)

Four steps:

- Formulate the algorithmic goal as the root finding problem

$$\bar{f}(\theta^*) = 0$$

- if necessary, refine the design of  $\bar{f}$  to ensure that the associated ODE is **globally asymptotically stable**

$$\frac{d}{dt}\vartheta = \bar{f}(\vartheta)$$

$\theta$  for discrete settings,  $\vartheta$  for continuous settings.  
Both do the same job

- Is an **Euler-approximation** appropriate?

$$\theta_{n+1} = \theta_n + \alpha_{n+1} \bar{f}(\theta_n) \quad (1)$$

$\theta_{n+1}$  is the next iterate, not the next time step!

- Design an algorithm to approximate (1) based on whatever observation is available.

**Remark.** The idea is to transfer the global stability from the ODE to the algorithm.

**Goal:** Construct a vector field  $f$  such that  $\vartheta_t$  converges to the **target**  $\theta^* \in \mathbb{R}^d$ , where  $\theta^*$  is an equilibrium

$$f(\theta^*) = 0.$$

In ODE theory one uses so called **Picard-Iteration**

$$\vartheta_t^{n+1} = \vartheta_0 + \int_0^t f(\vartheta_\tau^n) d\tau, \quad 0 \leq t \leq T \quad (2)$$

based on

$$\vartheta_0 + \int_0^t f(\vartheta_\tau) d\tau, \quad 0 \leq t \leq T. \quad (3)$$

**Proposition 25.** Suppose that the function  $f$  is globally Lipschitz continuous:

$$\exists L > 0 : \forall x, y \in \mathbb{R}^d : \|f(x) - f(y)\| \leq L\|x - y\|$$

Then for each  $\theta_0$  there exists a unique solution to (3). in the finite time horizon. Moreover, successive approximation is uniformly convergent:

$$\lim_{n \rightarrow \infty} \max_{0 \leq t \leq T} \|\vartheta_t^n - \vartheta_t\| = 0$$

**Proposition 26** (Grönwall-Bellman-inequality). Let  $\alpha, \beta$  and  $z$  be non-negative functions defined

on  $[0, T]$ ,  $T > 0$ . Assume that  $\beta, z$  are continuous and that

$$z_t \leq \alpha_t + \int_0^t \beta_s z_s ds, \quad 0 \leq t \leq T$$

Then it holds

$$(i) \quad z_t \leq \alpha_t + \int_0^t \alpha_s \beta_s \exp\left(\int_s^t B_r dr\right) ds$$

(ii) if in addition the function  $\alpha$  is non-decreasing, then

$$z_t \leq \alpha_t \exp\left(\int_0^t B_s ds\right), \quad 0 \leq t \leq T$$

*Proof.* Both proofs can be found in any textbook on ODEs. The second one is also found in [2].  $\square$

**Proposition 27.** Consider  $\frac{d}{dt}\vartheta = f(\vartheta)$ ,  $\vartheta_0 = \theta_0$  with  $f$  globally Lipschitz. Then

*Not that nice, but at least a bound ...*

(i) There is a constant  $B_f$  depending only on  $f$  such that, with  $t \geq 0$

$$\|\vartheta_t\| \leq (B_f + \|\vartheta_0\|) e^{Lt} - B_f \quad (4)$$

$$\|\vartheta_t - \vartheta_0\| \leq \|B_f + L\|\vartheta_0\| t e^{Lt} \quad (5)$$

(ii) If there is an equilibrium  $\theta^*$ , then for each initial condition:

$$\|\vartheta_t - \theta^*\| \leq \|\vartheta_0 - \theta^*\| e^{Lt} \quad (6)$$

*Proof.* (ii): use 3 to get

$$\vartheta_t - \theta^* = \vartheta_0 - \theta^* + \int_0^t f(\vartheta_\tau) d\tau$$

Since  $f(\theta^*) = 0$ , we see

$$\begin{aligned} \|f(\vartheta_\tau)\| &= \|f(\vartheta_\tau) - f(\theta^*)\| \\ &\leq L \underbrace{\|\vartheta_\tau - \theta^*\|}_{=: z_\tau} \end{aligned}$$

So

$$z_t \leq z_0 + L \int_0^t z_\tau d\tau.$$

Using proposition 26 (ii) with  $\beta_t \equiv L$ ,  $\alpha_t \equiv z_0$  we get

$$\|\vartheta_t - \theta^*\| \leq \|\vartheta_0 - \theta_0\| \exp(Lt)$$

(i): take any  $\bar{\theta} \in \mathbb{R}^d$  and use the Lipschitz continuity

$$\begin{aligned} \|f(\theta)\| &\leq \|f(\theta) - f(\bar{\theta})\| + \|f(\bar{\theta})\| \\ &\leq L\|\theta - \bar{\theta}\| + \|f(\bar{\theta})\| \\ &\leq L\|\theta\| + L\|\bar{\theta}\| + \|f(\bar{\theta})\|. \end{aligned}$$

For any fixed  $\bar{\theta}$ , define  $B_f = \|\bar{\theta}\| + \|f(\bar{\theta})\|/L$  which gives

$$\|f(\theta)\| \leq L[\|\theta\| + B_f], \quad \theta \in \mathbb{R}^d$$

using (3)

$$\begin{aligned} \|\vartheta_t\| + B_f &\leq \|\vartheta_0\| + B_f + \underbrace{L}_{\beta} \int_0^t \left[ \underbrace{\|\vartheta_\tau + B_f\|}_{z_\tau} \right] d\tau \\ &\leq [\|\vartheta_0\| + B_f] \exp(Lt) \end{aligned}$$

where the last step follows by the same trick as in (ii), i.e. by using Grönwall.  $\square$

## 2.2 Euler's method once more

$$\frac{\hat{\vartheta}_{t_{n+1}} - \hat{\vartheta}_{t_n}}{\alpha_{n+1}} = f(\hat{\vartheta}_{t_n}), \quad \hat{\vartheta}_0 = \vartheta_0 = \theta_0 \quad (7) \quad \begin{array}{l} \text{Explicit Euler, implicit} \\ \text{Euler is nicer to analyze} \end{array}$$

or

$$\hat{\vartheta}_{t_{n+1}} = \hat{\vartheta}_{t_n} + \alpha_{n+1} f(\hat{\vartheta}_{t_n})$$

It can be shown for  $f$  globally Lipschitz

$$\max_{0 \leq t \leq T} \|\hat{\vartheta}_t - \vartheta_t\| \leq \underbrace{K(L, T)}_{\text{exponential in } L, T} \max\{\alpha_k \mid t_k < T\} \quad (8)$$

## 2.3 Optimization

**Goal:** Find, for some loss function  $\Gamma : \mathbb{R}^d \rightarrow \mathbb{R}_+$ ,

$$\theta^* \in \operatorname{argmin} \Gamma(\theta). \quad (9)$$

Use steepest-descent, formulated as ODE

$$\frac{d}{dt} \vartheta = -\nabla_{\theta} \Gamma(\theta) \quad (10)$$

so called gradient flow.

$$\nabla \Gamma(\theta_0) \perp \{\theta \in \mathbb{R}^d \mid \Gamma(\theta) = \Gamma(\theta_0)\} =: S_{\Gamma}(\theta_0)$$

The gradient flow steers into the interior of  $S_{\Gamma}(\theta_0)$ .

**Definition 28.** (i) A set  $S \subset \mathbb{R}^d$  is convex if it contains all line segments with endpoints in  $S$

(ii) A function  $\Gamma : S \rightarrow \mathbb{R}$  with  $S$  convex, is called convex if for any  $\theta^0, \theta^1 \in S$  and  $\rho \in (0, 1)$

$$\Gamma((1 - \rho)\theta^0 + \rho\theta^1) \leq (1 - \rho)\Gamma(\theta^0) + \rho\Gamma(\theta^1)$$

$\Gamma$  is strictly convex if this inequality is strict whenever  $\theta^0 \neq \theta^1$

(iii) If  $\Gamma$  is differentiable, then it is called strongly convex if for  $\delta_0 > 0$

$$\langle \nabla \Gamma(\theta) - \nabla \Gamma(\theta^0), \theta - \theta^0 \rangle \geq \delta_0 \|\theta - \theta_0\|^2, \quad \forall \theta, \theta^0 \in S$$

From numerical optimization we know:

**Theorem 29.** Suppose that  $\Gamma : \mathbb{R}^d \rightarrow \mathbb{R}$  is convex. Then for given  $\theta^0 \in \mathbb{R}^d$

(i) if  $\theta^0$  is a local minima, then it is also a global minimum

(ii) if  $\Gamma$  is differentiable at  $\theta^0$ , with  $\nabla \Gamma(\theta) = 0$ , then  $\theta^0$  is a global minimum

(iii) if either (i) or (ii) hold, and if  $\Gamma$  is strictly convex, then  $\theta^0$  is the unique global minimum

**Proposition 30.** Suppose that  $\Gamma$  is continuously differentiable, convex and coercive, with unique minimizer  $\theta^*$ . Then the gradient flow

$$\frac{d}{dt} \vartheta = -\nabla \Gamma(\vartheta)$$

is globally asymptotically stable, with unique equilibrium  $\theta^*$ .

If  $\Gamma$  is strongly convex, then the rate of convergence is exponential

$$\|\vartheta_t - \theta^*\| \leq e^{-\delta_0 t} \|\vartheta_0 - \theta^*\|,$$

where  $\delta_0$  comes from theorem 29.

*Proof.* We use as Lyapunov function  $V(\theta) = \frac{1}{2}\|\theta - \theta^*\|^2$ . From the chain rule

$$\frac{d}{dt}V(\vartheta_t) = -\nabla_{\theta}\Gamma(\vartheta_t)^{\top} [\vartheta_t - \theta^*]$$

By convexity we get the following bound

$$\Gamma(\theta^*) \geq \Gamma(\vartheta_t) + \nabla_{\theta}\Gamma(\vartheta_t)^{\top} [\theta^* - \vartheta_t]$$

using the support condition this becomes

$$\frac{d}{dt}V(\vartheta_t) \leq \Gamma(\theta^*) - \Gamma(\vartheta_t) \leq 0$$

since  $\theta^*$  is the minimum. The strict inequality ( $< 0$ ) holds when  $\vartheta_t \neq \theta^*$ .  $V$  fulfills definition 20 and proposition 21 gives global asymptotic stability.

Under strict convexity

Coercive, therefore  
inf-compact

$$\begin{aligned} \frac{d}{dt}V(\vartheta_t) &= - \left[ \nabla_{\theta}\Gamma(\vartheta_t) - \underbrace{\nabla_{\theta}\Gamma(\theta^*)}_{=0} \right]^{\top} [\vartheta_t - \theta^*] \\ &\stackrel{\text{strong convexity}}{\leq} -\delta_0 \|\vartheta_t - \theta^*\|^2 = -2\delta_0 V(\vartheta_t) \end{aligned}$$

This implies  $V(\vartheta_t) \leq V(\vartheta_0) \exp(-2\delta_0 t) \forall t$  by integrating.  $\square$

**Theorem 31.** *If the Polyak-Lojasiewicz (PL) inequality*

$$\frac{1}{2}\|\nabla\Gamma(\theta)\|^2 \geq \mu|\Gamma(\theta) - \Gamma(\theta^*)| \quad (11)$$

*holds then the gradient flow satisfies for each initial  $\vartheta_0$*

$$\Gamma(\vartheta_t) - \Gamma^* \leq e^{-\mu t}(\Gamma(\vartheta_0) - \Gamma^*).$$

*If in addition  $\Gamma$  is coercive, then the solutions are bounded and any limit point  $\theta_{\infty}$  of  $\{\vartheta_t\}$  is an optimizer*

$$\Gamma(\theta_{\infty}) = \Gamma^*$$

*Used in stochastic  
gradient descent*

*Proof.* We use  $V(\theta) = \frac{1}{2}|\Gamma(\theta) - \Gamma^*|$  for the Lyapunov function.

$$\begin{aligned} \implies \frac{d}{dt}V(\vartheta_t) &= \frac{1}{2}\nabla_{\theta}\Gamma(\vartheta_t)^{\top} \frac{d}{dt}\vartheta_t \\ &= -\frac{1}{2}\|\nabla\Gamma(\vartheta_t)\|^2 \leq -\mu V(\vartheta_t) \end{aligned}$$

This implies using the same technique as in the previous proof

$$\begin{aligned} \frac{1}{2}[\Gamma(\vartheta_t) - \Gamma^*] &= V(\vartheta_t) \leq e^{-\mu t}V(\vartheta_0) \\ &= e^{-\mu t} \frac{1}{2}[\Gamma(\vartheta_0) - \Gamma^*] \end{aligned}$$

If  $\Gamma$  is coercive, then trajectories of  $\vartheta$  evolve in the compact set  $S = \{\theta \mid V(\theta) \leq V(\vartheta_0)\}$ . If  $\theta_{\infty}$  is a limit point  $\theta_{\infty} = \lim_{n \rightarrow \infty} \vartheta_{t_n}$  for  $t_n \rightarrow \infty$ . Using the continuity of the loss function, this implies optimality:

$$\Gamma(\theta_{\infty}) = \lim_{n \rightarrow \infty} \Gamma(\vartheta_{t_n}) = \Gamma^* \quad \square$$

Consider the Euler method for the gradient flow:

$$\theta_{k+1} = \theta_k - \alpha \nabla \Gamma(\theta_k) \quad (12)$$

**Theorem 32.** Suppose that  $\Gamma$  satisfies

(i) the  $L$ -smooth inequality (LSI)

$$\Gamma(\theta') \leq \Gamma(\theta) + [\theta' - \theta]^\top \nabla \Gamma(\theta) + \frac{1}{2}L\|\theta' - \theta\|^2$$

(ii) the PL inequality 11

Then it holds for  $\alpha \leq \frac{1}{2}$

$$\Gamma(\theta_k) - \Gamma^* \leq (1 - \alpha\mu)^k [\Gamma(\theta_0) - \Gamma^*].$$

*Proof.*

$$\begin{aligned} \Gamma(\theta_{k+1}) - \Gamma(\theta_k) &\stackrel{\text{LSI}}{\leq} [\theta_{k+1} - \theta_k]^\top \nabla \Gamma(\theta_k) + \frac{1}{2}L\|\theta_{k+1} - \theta_k\|^2 \\ &\stackrel{12}{=} -\alpha\|\nabla \Gamma(\theta_k)\|^2 + \frac{1}{2}L\alpha^2\|\nabla \Gamma(\theta_k)\|^2 \\ &= (-\alpha + \frac{1}{2}L\alpha^2)\|\nabla \Gamma(\theta_k)\|^2 \end{aligned}$$

If  $\alpha \leq \frac{1}{L}$  then  $(-\alpha + \frac{1}{2}L\alpha^2) \leq \frac{1}{2}\alpha$

$$\begin{aligned} &\leq -\frac{1}{2}\alpha\|\nabla \Gamma(\theta_k)\|^2 \\ &\stackrel{\text{LSI}}{\leq} -\alpha\mu|\Gamma(\theta_k) - \Gamma^*| \end{aligned}$$

and therefore

$$\Gamma(\theta_{k+1}) - \Gamma^* \leq (1 - \alpha\mu)(\Gamma(\theta_k) - \Gamma^*)$$

after iterating  $k - 1$  times we obtain the result.  $\square$

**Lemma 33.** Suppose that  $\nabla \Gamma$  is globally Lipschitz

$$\|\nabla \Gamma(\theta') - \nabla \Gamma(\theta)\| \leq L\|\theta' - \theta\|, \quad \forall \theta, \theta' \in S$$

Then

(i)  $|\langle \nabla \Gamma(\theta') - \nabla \Gamma(\theta), \theta' - \theta \rangle| \leq L\|\theta' - \theta\|^2$

(ii) if  $S$  is convex, then  $\Gamma$  is  $L$ -smooth

*Proof.* (i)

$$\begin{aligned} |\langle \nabla \Gamma(\theta') - \nabla \Gamma(\theta), \theta' - \theta \rangle| &\leq \|\nabla \Gamma(\theta') - \nabla \Gamma(\theta)\| \|\theta' - \theta\| \\ &\leq L\|\theta' - \theta\|^2 \end{aligned}$$

(ii) for  $\theta', \theta \in S$  denote  $S \ni \theta^t := \theta + t(\theta' - \theta)$  and  $\xi^t = \Gamma(\theta^t)$ .

$\theta^t$  in  $S$ , since  $S$  is convex

$$\begin{aligned} \frac{d}{dt}\xi^t &= \langle \nabla \Gamma(\theta^t), \theta' - \theta \rangle \\ \frac{d}{dt}\xi^t - \frac{d}{dt}\xi^0 &= \langle \nabla \Gamma(\theta^t) - \nabla \Gamma(\theta^0), \theta' - \theta \rangle \\ &\stackrel{(i)}{\leq} tL\|\theta' - \theta\|^2 \end{aligned}$$

Now integrate

$$\begin{aligned} \Gamma(\theta') &= \xi^1 = \xi^0 + \int_0^1 \frac{d}{dt}\xi^t dt \\ &\leq \xi^0 + \frac{d}{dt}\xi^0 + \frac{1}{2}L\|\theta' - \theta\|^2 \\ &= \Gamma(\theta) + \langle \nabla \Gamma(\theta), \theta' - \theta \rangle + \frac{1}{2}L\|\theta' - \theta\|^2 \end{aligned} \quad \square$$

These are more general version of global Lipschitz and convexity

**Remark.** *Strong convexity:*

$$\langle \nabla \Gamma(\theta') - \nabla \Gamma(\theta), \theta' - \theta \rangle \geq \delta_0 \|\theta' - \theta\|^2$$

With  $D_\Gamma(y \mid x) = \Gamma(y) - \Gamma(x) + \langle \nabla \Gamma(x), y - x \rangle$  is the Bregman divergence.

$$\frac{\mu}{2} \|\theta' - \theta\|^2 \leq D_\Gamma(\theta' \mid \theta) \leq \frac{L}{2} \|\theta' - \theta\|^2$$

*This gives a bound on the loss function from both sides ...*

## 2.4 Quasi stochastic approximation

Assume there are observations  $\Phi_n \subset \Omega$ , which we might consider as realizations of a random variable  $\Phi$ . We have

$$f : \mathbb{R}^d \times \Omega \rightarrow \mathbb{R}^d$$

$$\bar{f}(\theta) := \mathbb{E}(\underbrace{f(\theta, \Phi)}_{\text{what we observe}}), \theta \in \mathbb{R}^d$$

As before we look for  $\bar{f}(\theta^*) = 0$

$$\frac{d}{dt} \vartheta_t = \bar{f}(\vartheta_t)$$

A key assumption is that what happens when following the state dynamics in any step depends only on the current state.

I.e. we have the Markov property

$$\Phi_n = [\cos(\omega n), \sin(\omega n)], \omega > 0$$

*Markov chain on the unit circle.* We will talk about the probing signal  $\xi$  and consider

$$\frac{d}{dt} \hat{\theta}_t = a_t f(\hat{\theta}_t, \xi_t) \quad (13)$$

the book uses  $\Theta$  instead of  $\hat{\theta}$

a quasistochastic approximation(QSA)-ODE,  $a_t$  is the step size.

For deterministic probing signals, we mainly consider two examples

Mixture of sin functions

$$\xi_t = \sum_{i=1}^K \overbrace{V^i}^{\in \mathbb{R}^m} \sin(2\pi[\Phi_i + \omega_i t])$$

Mixture of periodic functions, fixed  $K$ , phase  $\{\Phi_i\}$ , frequencies  $\{\omega_i\}$ .

$$\xi_t = \sum_{i=1}^K V^i [\Phi_i + \omega_i t]_{\text{modulo } 1}$$

Figure 2.1: Sketch 2.01

These signals have well defined steady-state means and covariance matrices.

Special case:  $\xi_t(i) = \sqrt{2} \sin(\omega_i t)$ ,  $1 \leq i \leq m$ ,  $\omega_i \neq \omega_j \forall i \neq j$ . Then the steady-state mean

$$\lim_{T \rightarrow \infty} \int_0^T \xi_t dt = 0$$

and covariance

$$\lim_{T \rightarrow \infty} \int_0^T \xi_i \xi_i^\top dt = \text{Id}$$

We now use a slightly different notation  $\hat{\theta}$  becomes  $\tilde{\theta}$ .

Start of lecture 09  
(13.05.2025)

$$\frac{d}{dt} \tilde{\theta}_t = a_t f(\tilde{\theta}, \xi_t) \quad (14)$$

$a_t$  non-negative.

Now consider integrating  $y : [0, 1] \rightarrow \mathbb{R}$ . Basic Monte-Carlo

$$\theta_n = \frac{1}{n} \sum_{i=0}^{n-1} y(\underbrace{\Phi(k)}_{\sim \text{Unif}([0,1])}) \quad (15)$$

A QSA approach is to use the saw tooth function

$$\xi_t = t(\text{modulo } 1).$$

Obtain estimate by

$$\tilde{\theta} = \frac{1}{t} \int_0^t y(\xi_t) dr \quad (16)$$

with a reasonable discretization afterwards.

To use (QSA-ODE (14))  $f(\theta, \xi) = y(\xi) - \theta$  with mean vector field

$$\begin{aligned} \bar{f}(\theta) &= \lim_{T \rightarrow \infty} \int_0^T f(\theta, \xi_t) dt \\ &= \int_0^1 y(\xi_t) dt - \theta \end{aligned}$$

which gives  $\theta^* = \int_0^1 y(\xi_t) dt$  as the unique root of  $\bar{f}$ . The QSA-ODE 14 is

$$\frac{d}{dt} \tilde{\theta}_t = a_t [y(\xi_t) - \tilde{\theta}_t]$$

(16) can be transformed into

$$\frac{d}{dt} \tilde{\theta}_t = \left[ -\frac{1}{t^2} \int_0^t y(\xi_r) dr + \frac{1}{t} y(\xi_t) \right] = \underbrace{\frac{1}{t}}_{\equiv a_t} [y(\xi_t) - \theta_t] \quad (17)$$

**Example.**  $y(\theta) = e^4(\sin(100\theta))$ , mean  $\theta^* \approx -0.5 \approx -0.48$ . Choose  $a_t = \frac{g}{1+t}$

## 2.5 Approximate Policy Improvement

nonlinear state model in continuous time:

$$\frac{d}{dt} x_t = f(x_t, u_t), t \geq 0 \quad (18)$$

$$J^*(x) = \min_{\underline{u}} \int_0^\infty c(x_t, u_t) dt, x = x_0 \quad (19)$$

Given feedback law  $u_t = \phi(x_t)$ , we have

$$J^\phi(x) = \int_0^\infty c(x_t, \phi(x_t)) dt, x = x_0 \quad (20)$$

**Proposition 34.** If  $J$  is finite, then for each initial condition  $x_0$  and each  $t$

$$\frac{d}{dt} J(x_t) = -c(x_t)$$

If  $J$  is continuously differentiable, then the Lyapunov bound  $\frac{d}{dt} V(x_t)$  from definition 20 follows with equality

$$\nabla J(x) f(x) = -c(x)$$

*Proof.* For any  $T > 0$ ,  $J(x_0) = \int_0^T c(x_r) dr + J(x_T)$ . For  $t \geq 0, \delta > 0$  given, use  $T = t + \delta$  and  $T = t$  and subtract:

$$\begin{aligned} 0 &= J(x_0) - J(x_0) = \int_t^{t+\delta} c(x_r) dr + (J(x_{t+\delta}) - J(x_t)) \\ &= \underbrace{\frac{1}{\delta} \int_t^{t+\delta} c(x_r) dr}_{\xrightarrow{\delta \rightarrow 0} c(x_t)} + \underbrace{\frac{1}{\delta} (J(x_{t+\delta}) - J(x_t))}_{\xrightarrow{\delta \rightarrow 0} \frac{d}{dt} J(x_t)} \\ &\implies \frac{d}{dt} J(x_t) = -c(x_t) \end{aligned}$$

Using the chain rule yields the second equation. □

For  $J^\phi$  we have

$$0 = c(x, \phi(x)) + \nabla J^\phi(x) \cdot f(x, \phi(x))$$

### Policy Improvement in continuous time:

$$\phi^+(x) \in \operatorname{argmin}_u \left\{ \underbrace{c(x, u) + \nabla J(x) \cdot f(x, u)}_{\text{need to approximate by } Q^\phi(x, u)} \right\}$$

Now aim for updating of  $Q$ -function. Add to the above  $J^\phi$  on both sides

$$J^\phi(x) = J^\phi(x) + c(x, \phi(x)) + \nabla J^\phi(x) \cdot f(x, \phi(x))$$

We solved for the optimal  $Q$ -function by using a fixed point equation, with  $\underline{Q}^\phi(x) = Q^\phi(x, \phi(x))$  we write

$$Q^\phi(x, u) = \underline{Q}^\phi(x) + c(x, u) + \nabla \underline{Q}^\phi(x) f(x, u).$$

$\underline{Q}$  for the fixed, but optimal choice of  $u$

Consider  $\{Q^\theta \mid \theta \in \mathbb{R}^d\}$  family of approximations. Bellman errors (Temporal differences expressions?) gives

$$B^\theta(x_t, u_t) = -Q^\theta(x_t, u_t) + \underline{Q}^\theta(x) + c(x_t, u_t) + \underbrace{\nabla \underline{Q}^\theta(x) f(x_t, u_t)}_{= \frac{d}{dt} Q^\theta(x_t)} \quad (21)$$

Everything on the RHS is can be observed for any state-action pair without knowledge of  $f$ .  
Now, find  $\theta^*$  that minimizes

$$\|B^\theta\|^2 = \lim_{T \rightarrow \infty} \frac{1}{T} \int_0^T [B^\theta(x_t, u_t)]^2 dt$$

Choose feedback law with exploration  $u_t = \tilde{\phi}(x_t, \xi_t)$ . Assuming bounded state trajectories, such that (21) exists, define  $\Gamma(\theta) = \frac{1}{2} \|B^\theta\|^2$ , we get

$$0 \stackrel{!}{=} \nabla \Gamma(\theta) = \lim_{t \rightarrow \infty} \int_0^T [B^\theta(x_t, u_t)] \nabla_\theta B^\theta(x_t, u_t) dt$$

Gradient flow

$$\frac{d}{dt} \vartheta_t = -\nabla_\theta \Gamma(\vartheta_t)$$

QSA counterpart is (21) with probing signal

$$\frac{d}{dt} \tilde{\theta}_t = -a_t B^{\tilde{\theta}_t}(x_t, u_t) \kappa_t^{\tilde{\theta}_t}$$

with

$$\begin{aligned} \kappa_t^{\tilde{\theta}_t} &= \nabla_\theta B^{\tilde{\theta}_t}(x_t, u_t) \\ &= -\nabla_\theta Q^\theta(x_t, u_t) + \{\nabla_\theta Q^\theta(x_t, \phi(x_t)) + \frac{d}{dt} \nabla_\theta Q^\theta(x_t, \phi(x_t))\} \end{aligned}$$

assuming we can exchange differentiation w.r.t time and w.r.t  $\theta$ .  
(QSA-ODE)

$$\frac{d}{dt} \tilde{\theta}_t = a_t f(\tilde{\theta}_t, \xi_t)$$

aim to relate this to

$$\frac{d}{dt} \vartheta_t = \bar{f}(\vartheta_t).$$

**Lemma 35.** Define the change of variables

$$\tau = s_t := \int_0^t a_r dr, \quad t \geq t_0.$$

Let  $\{\vartheta_\tau \mid \tau \geq \tau_0\}$  the solution to the ODE above initialized to  $\tau_0 = s_{t_0}$  with  $\vartheta_{\tau_0} = \tilde{\theta}_{t_0}$ . The solution to

$$\frac{d}{dt} \bar{\theta}_t = a_t \bar{f}(\bar{\theta}_t), \quad t \geq t_0, \quad \bar{\theta}_{t_0} = \tilde{\theta}_{t_0}$$

is given by  $\bar{\theta}_t = \vartheta_\tau$ .

*Proof.* Change of variables and observing that

$$d\tau = a_t dt.$$

□

Recall  $\bar{f}(\theta) := \lim_{T \rightarrow \infty} \int_0^T f(\theta, \xi_t) dt$  for all  $\theta \in \mathbb{R}^d$ . Remember the temporal transformation

Start of lecture 10  
(15.05.2025)

$$\tau = s_t = \int_0^t a_r dr$$

and lemma 35. Define  $\hat{\theta}_\tau = \tilde{\theta}(s^{-1}(\tau)) = \tilde{\theta}_t|_{t=s^{-1}(\tau)}$ . By the chain rule and observing that  $d\tau = a_t dt$  yields

$$\frac{d}{d\tau} \hat{\theta}_\tau = \frac{d}{d\tau} \tilde{\theta}(s^{-1}(\tau)) = f(\tilde{\theta}(s^{-1}(\tau)), \xi(s^{-1}(\tau))).$$

$\hat{\theta}, \tilde{\theta}$  differ only by a time scaling, so convergence of the one yields convergence of the other.

**Lemma 36.** Consider the original ODE

$$\frac{d}{dt} \vartheta_t = \bar{f}(\vartheta_t) \quad (22)$$

and assume  $f$  is locally Lipschitz with constant  $L_f$ . Then there exists a constant  $B_f$  depending only on  $f$ , such that

Version of proposition 27

$$\|\hat{\theta}_t - \hat{\theta}_0\| \leq (B_f + L_f \|\hat{\theta}_0\|) t e^{L_f t}, \quad t \geq 0$$

*Proof.* Proof of proposition 27 in adapted notation.  $\square$

Now, denote by  $\vartheta_w^\tau, w \geq \tau$  the unique solution to (22):

$$\frac{\partial}{\partial w} \vartheta_w^\tau = \bar{f}(\vartheta_w^\tau), \quad w \geq \tau, \quad \vartheta_\tau^\tau = \hat{\theta}_\tau$$

with that we get

quasistochastic vs  
continuous

1.  $\vartheta_{\tau+v}^\tau = \hat{\theta}_\tau + \int_0^{\tau+v} \bar{f}(\vartheta_w^\tau) dw, \quad \tau, v \geq 0$
2.  $\hat{\theta}_{\tau+v} = \hat{\theta}_\tau + \int_\tau^{\tau+v} f(\hat{\theta}_w, \xi(s^{-1}(w))) dw, \quad \tau, v \geq 0$

The following assumptions will be used in the following:

**QSA1** The process  $a$  is non-negative, monotonically decreasing and  $\lim_{t \rightarrow \infty} a_t = 0, \int_0^\infty a_r dr = \infty$

it does not go to zero too fast

**QSA2** The functions  $\hat{f}, f$  are Lipschitz continuous with constant  $L_f$ :

$$\begin{aligned} \|\bar{f}(\theta') - \bar{f}(\theta)\| &\leq \|L_f\| \|\theta' - \theta\| \\ \|f(\theta', z) - f(\theta, z)\| &\leq \|L_f\| \|\theta' - \theta\| \end{aligned}$$

for all  $\theta, \theta' \in \mathbb{R}^d, z \in \Omega$  and there exists a Lipschitz continuous functions  $b_0 : \mathbb{R}^d \rightarrow \mathbb{R}_+$ , such that for all  $\theta \in \mathbb{R}^d$

Is my probing covering everything: ergodicity, ergodic bound

$$\left\| \int_{t_0}^{t_1} f(\theta, \xi_t) - \bar{f}(\theta) dt \right\| \leq b_0(\theta), \quad 0 \leq t_1 \leq t_1$$

**QSA3** The ODE  $\frac{d}{dt} \vartheta_t = \bar{f}(\vartheta_t)$  has a globally asymptotically stable equilibrium  $\theta^*$

Consider first, arbitrary  $\theta$

**Lemma 37.** Assume (QSA1), (QSA2) hold for any fixed  $T > 0$  and  $\theta \in \mathbb{R}^d$ .

There is a connection to the law of large numbers  
...

$$\left\| \int_\tau^{\tau+T} [f(\theta, \xi(s^{-1}(w))) - \bar{f}(\theta)] dw \right\| \leq b_0(\theta) \epsilon_\tau^f,$$

where  $\epsilon_\tau^f = 3a_t|_{t=s^{-1}(\tau)}$  and  $b_0$  comes from (QSA2).

*Proof.* Set  $\tilde{f}_w(\theta) = f(\theta, \xi_w) - \bar{f}(\theta)$  for each  $w, \theta$ . Write

large  $\epsilon_t$  in the book?  
Prob.  $\mathcal{E}$

$$E_t = \int_0^t \tilde{f}_w(\theta) dw.$$

By assumptions  $\|E_t\| \leq b_0(\theta)$ ,  $t \geq 0$ .

$$\begin{aligned} \int_{t_0}^{t_1} a_t \tilde{f}_t(\theta) dt &\stackrel{\text{IbP}}{=} a_t E_t \Big|_{t_0}^{t_1} - \int_{t_0}^{t_1} |a'_t| E_t dt \\ \left\| \int_{t_0}^{t_1} a_t \tilde{f}_t(\theta) dt \right\| &\leq a_{t_0} \|E_{t_0}\| + a_{t_1} \|E_{t_0}\| + \int_{t_0}^{t_1} |a'_t| E_t dt \\ &\stackrel{a \text{ decreasing}}{\leq} 2a_{t_0} b_0(\theta) - b_0(\theta) \int_{t_0}^{t_1} a'_t dt \\ &\leq 3a_{t_0} b_0(\theta) \end{aligned}$$

Set  $t_0 = s^{-1}(\tau)$ ,  $t_1 = s^{-1}(\tau + T)$ ,  $t = s^{-1}(w)$ , giving  $dw = a_t dt$

$$\begin{aligned} \left\| \int_{\tau}^{\tau+T} [f(\theta, \xi(s^{-1}(w))) - \bar{f}(\theta)] dw \right\| &= \left\| \int_{t_0}^{t_1} a_t \tilde{f}_t(\theta) dt \right\| \\ &\leq 3a_{t_0} b_0(\theta) = \epsilon_{\tau}^f b_0(\theta) \end{aligned}$$

□

**Proposition 38.** Assuming that  $\hat{\theta}$  is bounded. Then for any  $T > 0$

$$\lim_{\tau \rightarrow \infty} \sup_{v \in [0, T]} \left\| \overbrace{\int_{\tau}^{\tau+v} [f(\hat{\theta}_w, \xi(s^{-1}(w))) - \bar{f}(\hat{\theta}_w)] dw}^{E_{\tau+v}^{\tau}} \right\| = 0$$

and

$$\lim_{\tau \rightarrow \infty} \sup_{v \in [0, T]} \left\| \hat{\theta}_{\tau+v} - \vartheta_{\tau+v}^{\tau} \right\| = 0$$

*Proof.* We use piecewise constant approximation, as in Riemannian integration, and set for  $\delta > 0$ ,  $\tau_k = \tau + k\delta$ ,  $k \geq 0$

$$E_{\tau+v}^{\tau} = \sum_{k=0}^{n_v-1} \int_{\tau_k}^{\tau_{k+1}} [f(\hat{\theta}_{\tau_k}, \xi(s^{-1}(w))) - \bar{f}(\hat{\theta}_{\tau_k})] dw + \epsilon_v^{\tau},$$

which holds due to (QSA1), Lipschitz condition,  $n_v = \lfloor \frac{v}{\delta} \rfloor$ . and

$$\|\epsilon_v^{\tau}\| \leq b_L v \delta$$

for some finite constant  $b_L$ . Assuming  $\hat{\theta}$  is bounded, this bound is uniform in  $\tau$ . For fixed  $\hat{\theta}_{t_k}$  we can use lemma 37, so

$$\begin{aligned} \|E_{\tau+v}^{\tau}\| &\leq \sum_{k=0}^{n_v-1} \epsilon_{\tau_k}^f b_0(\hat{\theta}_{t_k}) + b_L v \delta \\ &\leq \epsilon_{\tau}^f \sum_{k=0}^{n_v-1} b_0(\hat{\theta}_{\tau_k}) + b_L v \delta \end{aligned}$$

Let  $b < \infty$  denote a constant such that  $b_0(\hat{\theta}_{\tau_k}) \leq b \forall \tau$ , which we can do since  $\hat{\theta}$  is bounded,  $b_0$  Lipschitz.

$$\|E_{\tau+v}^{\tau}\| \leq b \frac{v}{\delta} \underbrace{\epsilon_{\tau}^f}_{\xrightarrow{\tau \rightarrow \infty} 0 \text{ by QSA1}} + b_L v \delta$$

For any  $T > 0$

$$\lim_{\tau \rightarrow \infty} \sup_{v \in [0, T]} \|E_{\tau+v}^\tau\| \leq 0 + b_L T \delta$$

Since  $\delta > 0$  was arbitrary, we have the first statement.

For the second limit:  $E_r^\tau = \vartheta_r^\tau - \hat{\theta}_r$ . The pair of identities after lemma 36 give using Lipschitz condition from (QSA2) we get

$$E_{\tau+v}^\tau = 0 + \int_\tau^{\tau+v} \bar{f}(\hat{\theta}_w) - f(\hat{\theta}_w, \xi(s^{-1}(w))) dw + \int_\tau^{\tau+v} \underbrace{\left[ \bar{f}(\vartheta_w^\tau) - \bar{f}(\hat{\theta}_w) \right]}_{\|\dots\| \leq L_f \|E_w^\tau\|} dw$$

$$\|E_{\tau+v}^\tau\| \leq \delta^\tau + L_f \int_\tau^{\tau+v} \|E_w^\tau\| dw,$$

where

$$\delta^\tau := \sup_{\tau' \geq \tau} \max_{0 \leq v \leq T} \left\| \int_{\tau'}^{\tau'+v} \left[ \bar{f}(\hat{\theta}_w) - f(\hat{\theta}_w, \xi(s^{-1}(w))) \right] dw \right\|$$

Grönwall's lemma gives

$$\|E_{\tau+v}^\tau\| \leq e^{L_f v} \delta^\tau, \quad 0 \leq v \leq 1$$

$\delta^\tau \rightarrow 0$  for  $\tau \rightarrow \infty$  due to the first statement.  $\square$

Start of lecture 11  
(20.05.2025)

**Theorem 39** (Boundedness implies convergence). *Suppose that (QSA1-QSA3) hold. Further assume **ultimate boundedness**, i.e. that a  $b < \infty$  exists, such that for each  $\theta \in \mathbb{R}^d$  and  $z \in \Omega$  there is a  $T_{\theta,z}$ , such that  $\|\hat{\theta}_\tau\| \leq b$  for all  $\tau \geq T_{\theta,z}$ , where  $\hat{\theta}_0 = \theta, \xi_0 = z$ . Then the solution to (14)*

$$\frac{d}{dt} \tilde{\theta}_t = a_t f(\tilde{\theta}_t, \xi_t)$$

*converges to  $\theta^*$  for each initial condition.*

*Proof.* Consider the time scaled  $\hat{\theta}_t$

$$\|\vartheta_\tau^\tau\| = \|\hat{\theta}_t\| \stackrel{\text{pA}}{\leq} b, \quad \tau \geq T_{\theta,z}$$

Using (QSA3), i.e.  $\frac{d}{dt} \vartheta_t = \bar{f}(\vartheta_t)$  has a globally asymptotically stable equilibrium  $\theta^*$ , we have that for every  $\epsilon > 0$ , there exists  $T_\epsilon > 0$  s.t.  $\|\vartheta_{\tau+v}^\tau - \theta^*\| < \epsilon \quad \forall v \geq T_\epsilon$ , whenever  $\|\vartheta_\tau^\tau\| \leq b$ . Then

$$\limsup_{\tau \rightarrow \infty} \|\hat{\theta}_{\tau+T_\epsilon} - \theta^*\| \leq \underbrace{\limsup_{\tau \rightarrow \infty} \|\hat{\theta}_{\tau+T_\epsilon} - \vartheta_{\tau+T_\epsilon}^\tau\|}_{\rightarrow 0 \text{ by proposition 38}} + \underbrace{\limsup_{\tau \rightarrow \infty} \|\vartheta_{\tau+T_\epsilon}^\tau - \theta^*\|}_{\leq \epsilon} \quad \square$$

**Lemma 40** (Weaker form of proposition 38 (ii)). *For some  $\bar{\delta} < \infty$  and any  $0 \leq T \leq 1$*

$$\|\hat{\theta}_{\tau+T} - \vartheta_{\tau+T}^\tau\| \leq e^{L_f T} b_0(\hat{\theta}_\tau) \epsilon_\tau^f + \bar{b}(1 + \|\hat{\theta}_\tau\|) T^2$$

*where  $b_0(\theta)$  and  $L_f$  are from (QSA2).*

*Proof.* Write  $E_r^\tau = \vartheta_r^\tau - \hat{\theta}_r$ ,  $r \geq T$ . The pair of identities after lemma 36 give, after inserting  $\pm \bar{f}(\theta_w)$

$$E_{\tau+T}^\tau = 0 + \int_\tau^{\tau+T} \left[ \bar{f}(\hat{\theta}_w) - f(\hat{\theta}_w, \xi(s^{-1}(w))) \right] dw + \int_\tau^{\tau+T} \left[ \bar{f}(\vartheta_w^\tau) - \bar{f}(\hat{\theta}_w) \right] dw$$

using (QSA2) we can bound

like last lecture ...

$$\begin{aligned}\|\bar{f}(\hat{\theta}_w) - \bar{f}(\hat{\theta}_\tau)\| &\leq L_f \|\hat{\theta}_w - \hat{\theta}_\tau\| \\ \|f(\hat{\theta}_w, \xi(s^{-1}(w))) - f(\hat{\theta}_\tau, \xi(s^{-1}(w)))\| &\leq L_f \|\hat{\theta}_w - \hat{\theta}_\tau\| \\ \|\bar{f}(\vartheta_w^\tau) - \bar{f}(\vartheta_w)\| &\leq L_f \|E_w^\tau\|\end{aligned}$$

With that, for any  $T > 0$  by inserting terms with  $\hat{\theta}_\tau$

$$\begin{aligned}\|E_{\tau+T}^\tau\| &\leq \left\| \int_\tau^{\tau+T} [\bar{f}(\hat{\theta}_\tau) - f(\hat{\theta}_\tau, \xi(s^{-1}(w)))] dw \right\| + 2L_f \int_\tau^{\tau+T} \|\hat{\theta}_w - \hat{\theta}_\tau\| + L_f \int_\tau^{\tau+T} \|E_w^\tau\| dw \\ &\leq \alpha_T^\tau + L_f \int_\tau^{\tau+T} \|E_w^\tau\| dw,\end{aligned}$$

where

$$\alpha_T^\tau := \underbrace{b_0(\hat{\theta}_\tau)}_{\text{from (QSA2)}} \epsilon_\tau^f + 2L_f \int_0^T \|\hat{\theta}_{\tau+w} - \hat{\theta}_\tau\| dw$$

Using Grönwall's lemma, proposition 26 (ii)

$$\|E_{\tau+T}^\tau\| \leq \alpha_T^\tau e^{L_f T}$$

Repeating the proof for proposition 27, we get

$$\|\hat{\theta}_{\tau+w} - \hat{\theta}_\tau\| \leq (B_f + L_f \|\hat{\theta}_\tau\|) w e^{L_f w}.$$

Increase  $e^{L_f w}$  to  $e^{L_f T}$  to get

$$\begin{aligned}2 \int_0^T \|\hat{\theta}_{\tau+w} - \hat{\theta}_\tau\| dw &\leq 2(B_f + L_f \|\hat{\theta}_\tau\|) e^{L_f T} \int_0^T w dw \\ &= (B_f + L_f \|\hat{\theta}_\tau\|) T^2 e^{L_f T}\end{aligned}$$

Hence

$$\alpha_T^\tau \leq b_0(\hat{\theta}_\tau) \epsilon_\tau^f + L_f (B_f + L_f \|\hat{\theta}_\tau\|) T^2 e^{L_f T}$$

Since  $0 \leq T \leq 1$ , we can find  $\bar{b} < \infty$  to bound  $L_f (B_f + L_f \|\hat{\theta}_\tau\|) T^2 e^{L_f T}$  by  $\bar{b}(1 + \|\hat{\theta}_\tau\|) T^2$ , where  $\bar{b}$  depends on fixed  $B_f, L_f$ .  $\square$

Reminder, **drift condition**

$$\langle \nabla f(\theta), f(\theta) \rangle < 0, \quad \theta \neq \theta^*$$

**Definition 41** (ultimately bounded). *The ODE*

$$\frac{d}{d\vartheta_t} = f(\vartheta_t), \quad \vartheta_0 = \theta_0$$

is called **ultimately bounded** if there exists a bounded set  $S \subset \mathbb{R}^d$ , such that for each initial condition  $\theta_0$ , there is a time  $T(\theta_0)$  such that  $\vartheta_t \in S \quad \forall t \geq T(\theta_0)$ .

**Proposition 42.** Assume that there is a continuously differentiable function  $V : \mathbb{R}^d \rightarrow \mathbb{R}_+$  satisfying the Lyapunov condition

$$\langle \nabla V(\theta), f(\theta) \rangle \leq -\delta_0, \quad \theta \in S^c$$

for some  $\delta_0 > 0$  and some set  $S \subset \mathbb{R}^d$ . Then  $T_S(\theta) \leq \delta_0^{-1} V(\theta)$  for  $\theta \in \mathbb{R}^d$ , where

$$T_S(\theta) = \min\{t \mid \vartheta_t \in S\}, \quad \vartheta_0 = \theta \in \mathbb{R}^d.$$

If in addition  $S$  is compact and  $V$  inf-compact, then the corresponding ODE is ultimately bounded.

*Lyapunov function*

*If we are not in  $S$ , we are getting pointed into that direction*

**first entrance time**  $T_S$

*Proof.* Assume  $\delta_0 = 1$  w.l.o.g., we interpret the condition as *along a path*

$$\frac{d}{dt}V(\vartheta_t) \leq 1,$$

for  $0 \leq t \leq T_S(\theta)$ ,  $\vartheta_0 = \theta \in \mathbb{R}^d$ .  $T_N = \min(N, T_S(\theta))$ , integrate both sides from  $t = 0$  to  $t = T_N$ .

$$-V(\vartheta_0) \leq V(\vartheta_{T_N}) - V(\vartheta_0) \leq \int_0^{T_N} \frac{d}{dt}V(\vartheta_t)dt \leq -T_N$$

or  $\min(N, T_S(\theta)) \leq V(\vartheta_0)$ . Choosing  $N \geq V(\vartheta_0)$  gives the bound on the first entrance time:

$$T_S(\theta) \leq \delta_0^{-1}V(\theta).$$

Now we need to show that it stays in some  $S$ . Now,  $S$  is compact,  $V$  is inf-compact, so there exists  $N < \infty$  such that  $S \subset S_V(N) = \{\theta \mid V(\theta) \leq N\}$ , with  $S_V(N)$  compact as well. Hence

$$\langle \nabla V(\theta), f(\theta) \rangle \leq -1, \quad \theta \in \mathbb{R}^d, \quad V(\theta) \geq N$$

writing  $V(\theta) > N$  corresponds to  $\theta \in S_V(N)^c$ .

Now,  $V(\vartheta_t)$  is therefore decreasing, whenever  $\vartheta_t \in S_V(N)^c$ , this shows that the set  $S_V(N)$  is **absorbing**, which gives that

$$\vartheta_t \in S_V(N) \quad \forall t \geq T_S(\theta).$$

□

### Assumption (QSV):

There exists a continuous function  $V : \mathbb{R}^d \rightarrow \mathbb{R}$ , and constants  $c_0 > 0, \delta_0$  s.t. for any initial condition  $\vartheta_0$  of the ODE and  $0 \leq T \leq 1$  it holds for  $\|\vartheta_s\| > c_0$ , that

$$V(\vartheta_{s+T}) - V(\vartheta_s) \leq -\delta_0 \int_0^T \|\vartheta_{s+t}\| dt.$$

The Lyapunov function  $V$  is Lipschitz continuous with constant  $L_V$ .

If  $V$  is differentiable, then QSV implies

$$\frac{d}{dt}V(\vartheta_t) \leq -\delta_0 \|\vartheta_t\|,$$

whenever  $\|\vartheta_t\| > c_0$ .

QSV1 in the book

$V$  is strictly decreasing in that setting

**Lemma 43.** Assume  $V : \mathbb{R}^d \rightarrow \mathbb{R}_+$  is Lipschitz continuous and that for some constant  $T > 0$ ,  $0 < \delta_1 < 1$  and  $\tau_0, b < \infty$  it holds

$$V(\hat{\theta}_{\tau+T}) - V(\hat{\theta}_\tau) \leq -\delta_1 \|\hat{\theta}_\tau\|$$

for all  $\tau \geq \tau_0$ ,  $\|\hat{\theta}_\tau\| > b$ . Then the solution to the time-scaled ODE

$$\frac{d}{d\tau} \hat{\theta}_\tau = f(\hat{\theta}(s^{-1}(\tau)), \xi(s^{-1}(\tau))) \quad (23)$$

is ultimately bounded.

Start of lecture 12  
(22.05.2025)

*Proof.* For each initial condition  $\hat{\theta}_0 = \theta$  and  $\tau \geq \tau_0$ , denote by

$\hat{\tau} = \hat{\tau}(\theta, \tau) := \min(v \geq 0 \mid \|\hat{\theta}_{\tau+v}\| \leq b)$ , where  $\tau_0, b$  as before. For clarity, if  $\|\hat{\theta}_{\tau+v}\| > b$  for all  $v \geq 0$ , set  $\hat{\tau} = \infty$ .

For  $m \in \mathbb{Z}_+$ , define  $\hat{\tau}_m = \min(\hat{\tau}, m)$ . Then

$$\begin{aligned} -\hat{\tau}_m b \delta_1 &\geq -\delta_1 \int_\tau^{\tau+\tau_m} \underbrace{\|\hat{\theta}_w\|}_{\leq b} dw \\ &\geq \int_\tau^{\tau+\hat{\tau}_m} (V(\hat{\theta}_{w+T}) - V(\hat{\theta}_w)) dw \\ &= \int_{\tau+\hat{\tau}_m}^{\tau+\hat{\tau}_m+T} V(\hat{\theta}_w) dw - \int_\tau^{\tau+T} V(\hat{\theta}_w) dw \\ &\geq - \int_\tau^{\tau+T} V(\hat{\theta}_w) dw \end{aligned}$$

This bound is independent of  $m$ , holds for all  $\hat{\tau}_m$ . Therefore

$$\begin{aligned}\hat{\tau} &\leq \frac{1}{b\delta_1} \int_{\tau}^{\tau+T} V(\hat{\theta}_w) dw \\ \int_{\tau}^{\tau+T} V(\hat{\theta}_w) dw &\leq \int_{\tau}^{\tau+T} |V(\hat{\theta}_w) - V(\hat{\theta}_{\tau})| + |V(\hat{\theta}_{\tau})| dw \\ &\leq \int_{\tau}^{\tau+T} \underbrace{L_V \|\hat{\theta}_w\|}_{\text{prop 27: } \leq (C(V) + \|\hat{\theta}_{\tau}\|)c(L_V, T)} + L_V \|\hat{\theta}_{\tau}\| + |V(\hat{\theta}_{\tau})| dw\end{aligned}$$

So the integral can be bounded by constants depending on fixed values. So we can obtain a bound

$$\hat{\tau} \leq b_V(1 + \|\hat{\theta}_{\tau}\|).$$

Hence  $\hat{\tau}(\theta, \tau)$  is everywhere finite.

Denote by  $b_1 \sup\{\|\hat{\theta}_{\tau+v}\| \mid \tau \geq \tau_0, v \leq \hat{\tau}(\theta, \tau), \|\hat{\theta}_{\tau}\| \leq b+1\}$ . In words,  $b_1$  bounds the maximum norm of any breakout at time  $\tau$  if  $\hat{\theta}_{\tau} \in S = \{\theta \mid \|\theta\| \leq b+1\}$  and ends at the arrival time to the set

$$S_0 := \{\theta \mid \|\theta\| \leq b\}$$

denoted  $\tau + \hat{\tau}(\theta, \tau)$ .

Now every trajectory enters  $S_0 \subset S$  for some  $\tau \geq \tau_0$ , so it fulfills that  $\|\hat{\theta}_{\tau}\| \leq b_1$  for all  $\tau$  sufficiently large, which gives ultimate boundedness.  $\square$

**Proposition 44.** *Under (QSV), the solution to (23) is ultimately bounded, i.e. there exists some  $b < \infty$  such that for any*

$$\hat{\theta}_0 = \theta, \limsup_{\tau \rightarrow \infty} \|\hat{\theta}_{\tau}\| \leq b$$

*Proof.*  $V$  is from (QSV) and  $c_0$  the constant. For  $0 \leq T \leq 1$ ,  $\|\hat{\theta}_{\tau}\| \geq c_0 + 1$

$$\begin{aligned}V(\hat{\theta}_{\tau+T}) - V(\hat{\theta}_{\tau}) &= V(\hat{\theta}_{\tau+T}) - V(\vartheta_{\tau+T}^{\tau}) + V(\vartheta_{\tau+T}^{\tau}) - \underbrace{V(\vartheta_{\tau}^{\tau})}_{= \hat{\theta}_{\tau}} \\ &\leq |V(\hat{\theta}_{\tau+T}) - V(\vartheta_{\tau+T}^{\tau})| + V(\vartheta_{\tau+T}^{\tau}) - V(\vartheta_{\tau}^{\tau}) \\ &\leq L_V \|\hat{\theta}_{\tau+T} - \vartheta_{\tau+T}^{\tau}\| - \delta_0 \int_0^T \underbrace{\|\vartheta_{\tau+T}^{\tau}\|}_{\leq \|\hat{\theta}_{\tau}\| + \|\int_{\tau}^{\tau+T} \bar{f}(\vartheta_w^{\tau}) dw\|} dt \\ &\leq L_V \|\hat{\theta}_{\tau+T} - \vartheta_{\tau+T}^{\tau}\| - \delta_0 T \|\hat{\theta}_{\tau}\| \\ &\stackrel{\text{Lemma 40}}{\leq} L_V(e^{L_f} b_0(\hat{\theta}_{\tau}) \epsilon_{\tau}^f + \bar{b}(1 + \|\hat{\theta}_{\tau}\|)T^2) - \delta_0 T \|\hat{\theta}_{\tau}\|\end{aligned}$$

So, we can choose  $T > 0$  small enough and  $\tau_0$  large enough, so that

$$V(\hat{\theta}_{\tau+T}) - V(\hat{\theta}_{\tau}) \leq -\frac{1}{2}\delta_0 T \|\hat{\theta}_{\tau}\|, \quad \tau \geq \tau_0, \quad \|\hat{\theta}_{\tau}\| \geq c_0 + 1$$

and we can use the lemma 43.

$\square$  Now we can ultimate boundedness and therefore convergence!

## 2.6 Gradient free Optimization

Reminder:

$$\min_{\theta \in \mathbb{R}^d} \Gamma(\theta)$$

we assume it has a unique minimizer  $\theta^*$ .

$$\bar{f}(\theta) = \nabla \Gamma(\theta)$$

we look for  $\theta^*$  with  $\bar{f}(\theta^*) = 0$ . But, we are using  $f(\theta, \xi_t)$  due to lack of information. Generally, we design some  $\tilde{\nabla}_\Gamma(t)$  to approximate the above in an average sense

$$\int_{T_0}^{T_1} a_t \tilde{\nabla}_\Gamma(t) dt \approx \int_{T_0}^{T_1} a_t \nabla \Gamma(\tilde{\theta}_t) dt, \quad T_1 > T_0 > 0$$

and construct an ODE

$$\frac{d}{dt} \tilde{\theta}_t = -a_t \tilde{\nabla}_\Gamma(t) \quad (24)$$

We now assume  $\psi_t = \tilde{\theta}_t + \epsilon \xi_t$ ,  $t \geq 0, \epsilon \geq 0$  and we observe  $\Gamma(\psi_t)$  for each  $t$ . Here  $\psi_t$  is a  $d$ -dimensional probing signal.

We had

$$\lim_{T \rightarrow \infty} \frac{1}{T} \int_0^T \xi_t dt = 0, \quad \lim_{T \rightarrow \infty} \frac{1}{T} \int_0^T \xi \cdot \xi^\top dt = Id$$

### 2.6.1 Algorithm: quasi Stochastic Gradient Descent #1: qSGD #1

**Input:**  $d \times d$  pos. def. matrix  $G$ ,  $\tilde{\theta}_0 \in \mathbb{R}^d$

$\frac{d}{dt} \tilde{\theta}_t = -a_t \frac{1}{\epsilon} G \xi_t \Gamma(\psi_t)$ , where  $\psi_t = \tilde{\theta}_t + \epsilon \xi_t$ . In QSA-ODE we have therefore  $f(\theta_t, \xi_t) = -\frac{1}{\epsilon} G \xi_t \Gamma(\theta_t + \epsilon \xi_t)$  iff  $\Gamma \in C^2$ :

$$\Gamma(\theta + \epsilon \xi_t) = \Gamma(\theta) + \epsilon \xi_t^\top \nabla \Gamma(\theta) + \frac{1}{2} \epsilon^2 \xi_t^\top \nabla^2 \Gamma(\theta) \xi_t + o(\epsilon^2).$$

$$f(\theta, \xi_t) = -\frac{1}{\epsilon} G \xi_t \Gamma(\theta) - G \xi_t \xi_t^\top \nabla \Gamma(\theta) + O(\epsilon)$$

$$\underbrace{\lim_{T \rightarrow \infty} \frac{1}{T} \int_0^T f(\theta, \xi_t) dt}_{\bar{f}_\epsilon(\theta)} = 0 - G \nabla \Gamma(\theta) + O(\epsilon)$$

For  $G = Id$  qSGD#1 will approximate the steepest descent algorithm. In (QSA2) we assumed that  $f, \bar{f}$  are Lipschitz, but while  $\nabla \Gamma$  usually is Lipschitz,  $\Gamma$  often is not!

### 2.6.2 Algorithm: qSDG #3

For a given  $d \times d$  pos. def. matrix  $G$  and  $\tilde{\theta}_0 \in \mathbb{R}^d$

$$\frac{d}{dt} \tilde{\theta}_t = -a_t \frac{1}{2\epsilon} G \xi_t \left[ \Gamma(\tilde{\theta}_t + \epsilon \xi_t) - \Gamma(\tilde{\theta}_t - \epsilon \xi_t) \right] =: a_t f(\tilde{\theta}_t, \xi_t)$$

$f$  can be shown to be Lipschitz in  $\theta$ , whenever  $\nabla \Gamma$  is Lipschitz. In this case

$$f(\theta, \xi_t) = -G \xi_t \xi_t^\top \nabla \Gamma(\theta) + o(\epsilon), \quad \lim_{T \rightarrow \infty} \int_0^T f(\theta, \xi_t) dt = -G \nabla \Gamma(\theta) + o(\epsilon)$$

Start of lecture 13  
(27.05.2025)

**Proposition 45** (Global consistency). *Suppose that the following hold for  $\Gamma$  and the algorithm parameters in QSGD#3*

1. (QSA1) holds
2. The probing signal satisfies

$$\int_0^T \xi_t \xi_t^\top dt = Id$$

3.  $\nabla \Gamma$  is globally Lipschitz continuous, and  $\Gamma$  is strongly convex with unique minimizer  $\theta^* \in \mathbb{R}^d$

Control on both sides of  
the loss function ...

4. the corresponding QSA-ODE is ultimately bounded

Then there exists  $\bar{\epsilon} > 0$  s.t. for all  $\epsilon \in (0, \bar{\epsilon})$  there is a unique root  $\theta_\epsilon^*$  of  $\bar{f}_\epsilon$ , satisfying

$$\|\theta_\epsilon^* - \theta^*\| = O(\epsilon)$$

Moreover, convergence holds from each initial condition:

$$\lim_{t \rightarrow \infty} \theta_t = \theta_\epsilon^*$$

*Proof.* The assumptions imply that (QSA2) holds for

Exploit  $\nabla\Gamma$  is convex

$$f(\theta, \xi) = -G\xi\xi^\top \nabla\Gamma(\theta) + O(\epsilon)$$

$$\bar{f}_\epsilon(\theta) = \lim_{T \rightarrow \infty} \frac{1}{T} \int_0^T f(\theta, \xi) dt$$

$\Gamma$  is strongly convex, therefore there is an  $\epsilon_0 > 0$  s.t. there is a unique solution to  $G\nabla\Gamma(\theta) = z$ , whenever  $\|z\| \leq \epsilon_0$ . From this (QSA3, the asymptotic stability condition), can be established for  $\epsilon > 0$  small enough.

Theorem 39 yields that for each  $\epsilon > 0$ ,  $\theta_t$  converges to the unique root  $\theta_\epsilon^*$  of  $\bar{f}_\epsilon$  satisfying

$$\|\nabla\Gamma(\theta_\epsilon)\| = O(\epsilon)$$

From there, strong convexity gives

$$\Gamma(\theta^*) \geq \Gamma(\theta_\epsilon^*) + \nabla\Gamma(\theta_\epsilon^*)^\top (\theta^* - \theta_\epsilon^*) + \frac{\eta}{2} \|\theta_\epsilon^* - \theta^*\|^2$$

for some  $\eta > 0$ .

$$\begin{aligned} \frac{\eta}{2} \|\theta_\epsilon^* - \theta^*\|^2 &\leq \underbrace{\Gamma(\theta^*) - \Gamma(\theta_\epsilon^*)}_{\leq 0} + \nabla\Gamma(\theta_\epsilon^*)^\top (\theta^* - \theta_\epsilon^*) \\ &\leq \|\nabla\Gamma(\theta_\epsilon^*)\| \|\theta^* - \theta_\epsilon^*\| \end{aligned}$$

which gives

$$\|\theta_\epsilon^* - \theta^*\|^2 = O(\epsilon).$$

□

**Remark.** For the exam: About the structure of the proof / is it long / technical / which results does it use?

---

# Chapter 3:

## Value and $Q$ -Function approximation

### 3.1 A very short crash course in machine learning

#### How can we represent functions?

Goal:

$$h(x) = \sum_{i=1}^d \theta_i \psi_i(x).$$

We could also use neural networks, or kernels:

$$h(x) = \sum_{i=1}^d \theta_i k(x, x_i)$$

$$K_{ij} = k(x_i, x_j)$$

is a positive (semi)-definite matrix for each dataset.

For more information about kernels, you can look at my lecture notes for scientific computing 2 (also held by Garcke)

1. We need a way to represent a function  $h \in \mathcal{H}$

- linear
- neural networks
- piecewise polynomials
- kernels

2. loss  $\Gamma(h)$ ,  $\Gamma(h) = \Gamma(h(z_1), h(z_2), \dots, h(z_N))$  evaluated at some samples  $z_i$ ,  $1 \leq i \leq N$

3. algorithm to obtain  $\operatorname{argmin}_{h \in \mathcal{H}} \Gamma(h)$

Training data  $\{(z_i, y_i)\}_{i=1}^N$ ,  $y_i = h^*(z_i) + \epsilon_i$ ,

$$\Gamma(h) = \frac{1}{N} \sum_{i=1}^N (y_i - h(z_i))^2$$

We usually use **regularization** to avoid **overfitting**.

Always reserve samples for evaluating the quality of the prediction.

## 3.2 Reinforcement Learning

$$\mathcal{D}_{k+1}(Q^\theta) = -Q^\theta(x(k), u(k)) + c(x(k), u(k)) + \underbrace{Q^\theta(x(k+1))}_{=\min_u Q^\theta(x, u) \text{ or } Q^\theta(x(k+1), \phi(x(k+1)))}$$

We have a sequence of state-action pairs

$$\{\underbrace{x(k), u(k)}_{z_k} \mid 0 \leq k \leq N\}$$

$$\Gamma(h) = \frac{1}{N} \sum_{k=1}^N D_k(h(z_k), h(z_{k+1}))^2$$

where

$$D(h(z_k), h(z_{k+1})) := -h(x(k-1), u(k-1)) + c(x(k-1), u(k-1)) + \underline{h}(x(k))$$

with  $\underline{h}(x) = \min_u h(x, u)$ .

$$Q^\theta(x, u) = \theta^\top \Psi(x, u), \quad \theta \in \mathbb{R}^d$$

and  $\Psi$  a collection of basis functions  $\psi_i$ . Write

$$\begin{aligned} \gamma_k &= c(x(k), u(k)) \\ \tilde{\gamma}_{k+1} &= \Psi(x(k), u(k)) - \Psi(x(k+1), \phi(x(k+1))). \end{aligned}$$

Rewrite  $D_{k+1}(Q^\theta)$  as

$$\gamma_k = \tilde{\gamma}_{k+1}^\top \theta + \underbrace{D_{k+1}(Q^\theta)}_{:=\epsilon_k}$$

Since  $D_{k+1}(Q^\theta)$  will be small ...

This looks like a regression problem:

$$\Gamma(\theta) = \lim_{N \rightarrow \infty} \frac{1}{N} \sum_{k=0}^{N-1} \left[ \underbrace{\gamma_k - \tilde{\gamma}_{k+1}^\top \theta}_{=D_{k+1}(Q^\theta)} \right]^2$$

Look for  $\theta^* = \operatorname{argmin}_\theta \Gamma(\theta)$ .

### 3.2.1 Algorithm: Least Squares Temporal Difference Learning (LSTD)

For a given  $d \times d$  regularization matrix  $W$ ,  $W$  psd, integer  $N$ , and obtained samples  $\{(x(k), u(k)) \mid 0 \leq k \leq N\}$ , the minimizer is obtained.

One of three streams in RL

$$\theta_N^{\text{LSTD}} = \operatorname{argmin}_\theta \Gamma_N(\theta), \quad \Gamma_N(\theta) = \theta^\top W \theta + \frac{1}{N} \sum_{k=0}^{N-1} [\gamma_k - \tilde{\gamma}_{k+1}^\top(\theta)]^2 \quad (1)$$

$$Q^{\theta_N^{\text{LSTD}}} = \sum_{i=1}^d \theta_N^{\text{LSTD}}(\psi(i))$$

is the approximation of the  $Q$ -function.

We have a positive definite quadratic objective, so the solution to (1) can be obtained by solving for  $\nabla \Gamma(\theta) \stackrel{!}{=} 0$ .

**Proposition 46.** Define  $R_N = \frac{1}{N} \sum_{i=1}^N \tilde{\gamma}_i \tilde{\gamma}_i^\top$ ,  $\bar{\Psi}_N^\gamma = \frac{1}{N} \sum_{k=0}^{N-1} \tilde{\gamma}_{k+1} \gamma_k$ . Then  $\theta_N^{LSTD} = [\frac{1}{N} W + R_N]^{-1} \bar{\Psi}_N^\gamma$

The regularization  $W$  is introduced to ensure a unique solution.

Start of lecture 14  
(03.06.2025)

**Proposition 47** (Redundant Parametrization). Suppose that  $R_N = \frac{1}{N} \sum_{i=1}^N \tilde{\gamma}_i \tilde{\gamma}_i^\top$  has rank less than  $d$ . Then there is a non zero vector  $v \in \mathbb{R}^d$  for which the following two statements hold for each  $0 \leq k \leq N-1$ :

(i) For any  $\theta \in \mathbb{R}^d$  and  $r \in \mathbb{R}$ :

$$D_{k+1}(Q^\theta) = D_{k+1}(Q^{\theta'}),$$

where  $\theta' = \theta + rv$ .

(ii) From the on-policy implementation  $u(k) = \psi(x(k))$

$$v^\top \Psi(x(0), u(0)) = v^\top \Psi(x(k), u(k)).$$

*Proof.*  $R_N$  does not have full rank, therefore there exists  $v \neq 0$  s.t.

$$0 = v^\top R_N v = \frac{1}{N} \sum_{i=1}^N (v^\top \tilde{\gamma}_i)^2.$$

Therefore,  $v^\top \tilde{\gamma}_k = 0$  for every observed sample.

$$0 = v^\top \Psi(x(k), u(k)) - v^\top \Psi(x(k+1), \phi(x(k+1))), \quad 0 \leq k \leq N-1 \quad (2)$$

So,

$$\begin{aligned} D_{k+1}(Q^{\theta'}) &= -Q^{\theta'}(x(k), u(k)) + c(x(k), u(k)) + Q^{\theta'}(x(k+1), \phi(x(k+1))) \\ &= c(x(k), u(k)) + [\theta + rv] [-\Psi(x(k), u(k)) + \Psi(x(k+1), \phi(x(k+1)))] \\ &\stackrel{2}{=} c(x(k), u(k)) + \theta [-\Psi(x(k), u(k)) + \Psi(x(k+1), \phi(x(k+1)))] , \end{aligned}$$

which yields (i).

If  $u(k) = \phi(x(k))$ , use (2)

$$v^\top \Psi(x(k), u(k)) = v^\top \Psi(x(k+1), u(k+1))$$

repeated use for every  $k$  gives (ii). □

To avoid the convergence of the  $\Gamma(\theta) \rightarrow 0$  for long trajectories, one can do restarts.

### 3.2.2 Algorithms: LSTD-Learning with restarts

For a given  $d \times d$  matrix  $W > 0$ , integers  $N, M$ , and observed samples

$$\{x^i(k), u^i(k) \mid 0 \leq k \leq N, 1 \leq i \leq M\}$$

with user defined initial conditions

$$\{x^i(0) \mid 1 \leq i \leq M\}$$

and with action

$$u^i(k) = \tilde{\phi}(x^i(k), \xi^i(k))$$

the approximation  $Q^{\theta_N^{LSTD}} = \Psi^\top \theta_N^{LSTD}$  is obtained. Here

$$\theta_N^{LSTD} = \underset{\theta}{\operatorname{argmin}} \Gamma_N^i(\theta), \quad \Gamma_N(\theta) = \frac{1}{M} \sum_{i=1}^M \Gamma_N^i$$

and

$$\Gamma_N^i(\theta) = \theta^\top W \theta + \sum_{i=1}^{N-1} [\gamma_k^i - \xi \tilde{\gamma}_{k+1}^\top \theta]$$

It is fine not to probe at all

**Remark.** The LSTD algorithm can be formulated as a recursive algorithm

$$\theta_{N+1} = \theta_N + G_N \tilde{\gamma}_{N+1} (\gamma_N - \tilde{\gamma}_{N+1} \theta_N)$$

where

$$G_{N+1} = G_N - \frac{1}{K_{N+1}} G_N \tilde{\gamma}_{N+1} \tilde{\gamma}_{N+1}^T G_N$$

$$K_{N+1} = 1 + \tilde{\gamma}_{N+1}^T G_N \tilde{\gamma}_{N+1}$$

### 3.2.3 Galerkin relaxation

Basis  $\{\psi_i\}$ ,  $h^\theta(z) = \sum_{i=1}^d \theta_i \psi_i(z)$ , we want  $0 \stackrel{!}{=} \nabla_\theta \Gamma(h^\theta)$ .

For Bellmann error

$$0 = \frac{1}{N} \sum_{k=1}^N D_k(h^\theta(z_k), h^\theta(z_{k+1})) \zeta^\theta(k)$$

$$\zeta^\theta(k) = \nabla_\theta D_k(h^\theta(z_k), h^\theta(z_{k+1}))$$

Alternative is so-called Galerkin-relaxation, We construct a sequence  $\{\zeta(k)\}$ ,  $\zeta(k) \in \mathbb{R}^{d_\zeta}$

constraints

$$0 = \frac{1}{N} \sum_{k=1}^N D_k(h^\theta(z_k), h^\theta(z_{k+1})) \zeta_i(k) \quad 1 \leq i \leq d_\zeta$$

We relax  $D_k(h^\theta(z_k), h^\theta(z_{k+1})) = 0 \quad \forall k$

$\{\zeta(k)\}$  are called eligibility vectors in RL.

$\zeta(k)$  does not depend on  $\theta$ ,  $\zeta(k) \neq \zeta^\theta(k)$ , maybe  $\zeta(k) \approx \zeta^\theta(k)$ ,  $\theta \in \text{region of interest}$ . It can make sense to have  $d_\zeta = d$ , if  $\theta \in \mathbb{R}^d$ .

One can introduce them in at least one other way ...

## 3.3 Projected Bellman equation

Consider  $h^* = T(h^*)$ .

Reminder  $Q^n(x, u) = c(x, u) + Q^n(x^+, u^+)$ , where  $x^+ = F(x, u)$ ,  $u^+ = \phi(x^+)$ . In our notation  $Q^\theta(x, u)$ :

Motivated by the solution of the Bellmann equation

$$T(h)|_{(x,u)} = c(x, u) + h(x^+, u^+),$$

so  $Q^\theta = T(Q^\theta)$ . Consider an approximation in a function class  $\mathcal{H}$ .

$$\hat{h} = \hat{T}(\hat{h}) = P_{\mathcal{H}}(T(\hat{h})) \quad (3)$$

with  $P_{\mathcal{H}}(h) \in \mathcal{H}$  for  $h \in \mathcal{H}$ .

Or, consider a second function class  $\mathcal{G}$  and solve for  $\hat{h} \in \mathcal{H}$ :

$$0 = P_{\mathcal{G}}(\hat{h} - T(\hat{h})) \quad (4)$$

**Proposition 48.** Suppose that the following hold

- (i)  $\mathcal{H} = \mathcal{G}$
- (ii)  $\mathcal{H}$  is a linear function class, i.e.  $a_1 h_1 + a_2 h_2 \in \mathcal{H}$  for  $h_1, h_2 \in \mathcal{H}$ ,  $a_1, a_2 \in \mathbb{R}$
- (iii) The mapping  $P_{\mathcal{H}}$  is linear. For  $h_1, h_2 \in \mathcal{H}$ ,  $a_1, a_2 \in \mathbb{R}$ :

$$P_{\mathcal{H}}(a_1 h_1 + a_2 h_2) = a_1 P_{\mathcal{H}}(h_1) + a_2 P_{\mathcal{H}}(h_2)$$

Then the solution to (3) and (4) coincide.

*Proof.* Trivial □

We assume for  $g \in G$ :  $g : Z \rightarrow \mathbb{R}$ , and  $G$  is a linear function class. We further assume there is a state-process  $\Phi$  on  $Z$ , where  $(x(k), u(k), \xi(k)) = w(\Phi(k))$ , where  $w$  is Lipschitz. We define for a probability measure  $\omega$  with density  $\rho$

$$\langle h_1, h_2 \rangle_\omega = \mathbb{E}_\omega(h_1(\Phi), h_2(\Phi)) = \int_Z h_1(z) h_2(z) \rho(z) dz$$

$$\|h\|_\omega = \sqrt{\langle h, h \rangle_\omega}.$$

$$L_2(\omega) = \{h \mid \|h\|_\omega < \infty\}.$$

For any  $h \in L_2(\omega)$ , we define projection onto  $G$  as

$$\hat{h} = P_G(h) = \operatorname{argmin}_{g \in G} \{\|g - h\|_\omega\}.$$

For  $\hat{h} \in G$

$$\langle h - \hat{h}, g \rangle_\omega = 0, \quad g \in G$$

In particular, we assume that  $G$  has finite dimension. We choose  $d$  functions

$$\{\zeta_i \mid 1 \leq i \leq d\}$$

stack them to get  $\zeta : Z \rightarrow \mathbb{R}^d$  and define  $G\{g = \theta^\top \zeta \mid \theta \in \mathbb{R}^d\}$ .  $\zeta(k) := \zeta(\Phi(k))$  is the sequence of **eligibility vectors**.

We do not assume that  $d$  is the dimension of  $G$  in general

**Proposition 49.** Suppose that  $\zeta_i \in L_2(\omega)$  for each  $i$  and that the functions are linear independent in  $L_2^\omega$ . That is  $\|\zeta^\top \zeta\|_\omega = 0$ . For each  $h \in L_2(\omega)$ , the projection exists, is unique, and given by

$$\hat{h} = (\omega^\star)^\top \zeta$$

with  $\theta^\star = [R^\zeta]^{-1} \bar{\psi}^h$ ,  $\bar{\psi}^h \in \mathbb{R}^d$ ,  $\bar{\psi}_i^h = \langle \zeta_i, h \rangle_\omega$  *where*  $\mathbb{R}^{d \times d}$ ,  $R_{ij}^\zeta = \langle \zeta_i, \zeta_j \rangle_\omega$ .

*Sketch.* The orthogonality principle gives

$$\langle h - \hat{h}, \zeta_i \rangle_\omega = 0$$

we use this identity with  $\hat{h} = (\theta^\star)^\top \zeta$  □

**Proposition 50.**  $0 = P_G(\hat{h} - T(\hat{h}))$  holds if and only if

$$0 = \langle \zeta_i, \hat{h} - T(\hat{h}) \rangle_\omega \quad 1 \leq i \leq d.$$

This is the **Galerkin relaxation** of  $h^\star = T(h^\star)$  in the  $L_2(\omega)$  setting.

We saw this last time as well  $\psi$  like a Q-function

Consider  $\mathcal{H} = \{h = \theta^\top \psi \mid \theta \in \mathbb{R}^d\}$ , where  $\psi : X \times U \rightarrow \mathbb{R}$ . Now, we use the above on the Bellman operator.

$$0 = \mathbb{E}(\zeta_i(k)(\hat{h}(x(k), u(k)) - [c(x(k), u(k)) + \hat{h}(x(k+1), \phi(x(k+1)))]))$$

Solutions of this root finding problem define  $Q^{\theta^\star} \in \mathcal{H}$ .

Recall  $D_{k+1}$ , we can write equivalently

$$0 = \mathbb{E}(\zeta(k) D_{k+1}(Q^\theta))|_{\theta=\theta^\star}.$$

Given  $N$  observations, we approximate this by

More concrete Galerkin estimation

$$0 = \frac{1}{N} \sum_{k=0}^{N-1} \zeta(k) D_{k+1}(Q^\theta)|_{\theta=\theta^\star}.$$

### 3.3.1 Algorithm: TD( $\lambda$ )

Notation:  $\psi_{(k)} = \psi(x(k), u(k))$ ,  $c(k) = c(x(k), u(k))$ ,  $\zeta_k = \zeta(k)$

For a given  $\lambda \in [0, 1]$ , nonnegative step size sequence  $\{\alpha_n\}$ , initial conditions  $\theta_0, \zeta_0$  and observed samples  $\{x(k), u(k) \mid 0 \leq k \leq N\}$ , the sequence of estimates is defined by three coupled equations

$$\begin{aligned}\theta_{n+1} &= \theta_n + \alpha_{n+1} D_{n+1} \zeta_n \\ D_{n+1} &= -Q^{\theta_n}(x(n), u(n)) + c_n - Q^{\theta_n}(x(n+1), \phi(x(n+1))) \\ \zeta_{n+1} &= \lambda \zeta_n + \psi_{(n+1)}\end{aligned}$$

This was introduced differently, maybe we will also see this later. In all there are three views

This defines the approximation of the  $Q$ -function  $Q^{\theta_n} = \sum_{i=1}^d (\theta_n)_i \phi_i$ . We extend the state process

$$\Phi(k) = (x(k), u(k), \xi(k), \zeta(k)).$$

This means that  $\zeta(k)$  is a linear function of the state process  $\Phi(k)$ .

Denote  $\bar{f}_\lambda(\theta) = \mathbb{E}_\omega [\zeta(k) D_{k+1}(Q^\theta)]$ . TD( $\lambda$ ) is an approximation of the ODE

$$\frac{d}{dt} \vartheta = \bar{f}_\lambda(\vartheta) \quad (5)$$

$\bar{f}_\lambda(\theta) = A(\theta - \theta^*)$ , where  $A = \mathbb{E}_\omega [\zeta(k) [-\psi_{(k)} + \psi(x(k+1), \phi(k+1))]^\top]$ .

For linear systems QSV-assumptions can be shown if all eigenvalues of the systemmatrix have strictly negative real parts, i.e.  $A$  is Hurwitz.

This can be shown for the on-policy approach, so the algorithm converges. There is a counter example in the book if we are off-policy., so convergence of TD( $\lambda$ ) is not guaranteed in the off-policy setting.

### 3.3.2 Algorithm TD( $\lambda$ )-learning with nonlinear function approximation

In the setup as before in TD( $\lambda$ ),  $\theta_{n+1}, D_{n+1}$  are as for the linear case.

$$\begin{aligned}\zeta_{n+1} &= \lambda \zeta_n + \zeta_{n+1}^0 \\ \zeta_{n+1}^0 &= \nabla_\theta Q^\theta(x(n), u(n))|_{\theta=\theta_n}\end{aligned}$$

Observe that  $\zeta_n^0 = \Psi_{(n)}$  for a linear function class, so this is a consistent generalization. To extend, we use instead of the so far fixed policy  $\phi$

$\lambda = 0$  means we don't have a history at all! TD $\lambda$  is for a fixed policy

$$\phi_{(n)}^\theta = \underset{u}{\operatorname{argmin}} Q^\theta(x, u)$$

### 3.3.3 Algorithm: Q-learning

The change in comparison to TD( $\lambda$ ) is

$$D_{n+1}(Q^{\theta_n}) = -Q^{\theta_n}(x(n), u(n)) + c(k) - Q^{\theta_n}(x(n+1), \phi^{\theta_{n+1}})$$

A limit  $\theta^*$  will save  $\bar{f}(\theta^*) = 0$  with

$$\bar{f}(\theta) = \mathbb{E}_\omega [\zeta(k), D_{k+1}(Q^\theta)].$$

At first glance this looks as for TD( $\lambda$ ), but the last term of the update to  $D_{n+1}$  is different! For  $\lambda = 0$ , we can apply proposition 48 to conclude that  $Q^{\theta^*}$  solves

$$Q^{\theta^*} = P_{\mathcal{H}}(T(Q^{\theta^*})),$$

where  $T(Q)|_{(x,u)} = c(x, u) + \min_{u^+} Q(x^+, u^+)$  and  $x^+ = F(x, u)$ .

Theory for existence of a solution or stability (in the sense of global asymptotic stability) is so far lacking in the context of ODE analysis.
