Chapter 0:
Manuel's notes

Warning

These are unofficial lecture notes written by a student. They are messy, will almost surely contain errors, typos and misunderstandings and may not be kept up to date! I do however try my best and use these notes to prepare for my exams. Feel free to email me any corrections to mh@mssh.dev or s6mlhinz@uni-bonn.de.
Happy learning!

General Information

- Basis: Basis
- Website: https://ins.uni-bonn.de/teachings/ss-2025-467-v5e1-advanced-topics/
- Time slot(s): **Tuesday: 14-16** SR 2.035 and **Thursdays: 16-18** SR 2.035
- Exams: ?
- Deadlines: No exercise sheets / tutorials

0.1 Organization

Start of lecture 01 (10.4.2025)

- Focused on ingredients,won't get to the current state of the art
- Some algorithmic / numerical background (Euler method is fine)
- Control Problems (Steering the bike / car)

Chapter 1: Control Problems

1. u is the **control (input / action)**
2. y observations (outputs)
3. $\phi : Y \to U$ policy
4. ff feed forward control (plan we had)

Interactions with the outside world might be hidden in the observations. Typically ff is in regard to some reference state. There might be some disturbances (holes in the road, ...).
The overall aim is to find a policy ϕ that sticks close to $r(k), k \geq 0$.

t is continous, k is step by step / iterative

$$u(k) = u_{\text{ff}}(k) + U_{fb}(k)$$

where u_{ff} is the planing to reach the overall goal and u_{fb} actual steering, updated "all the time".
Some examples from the book:

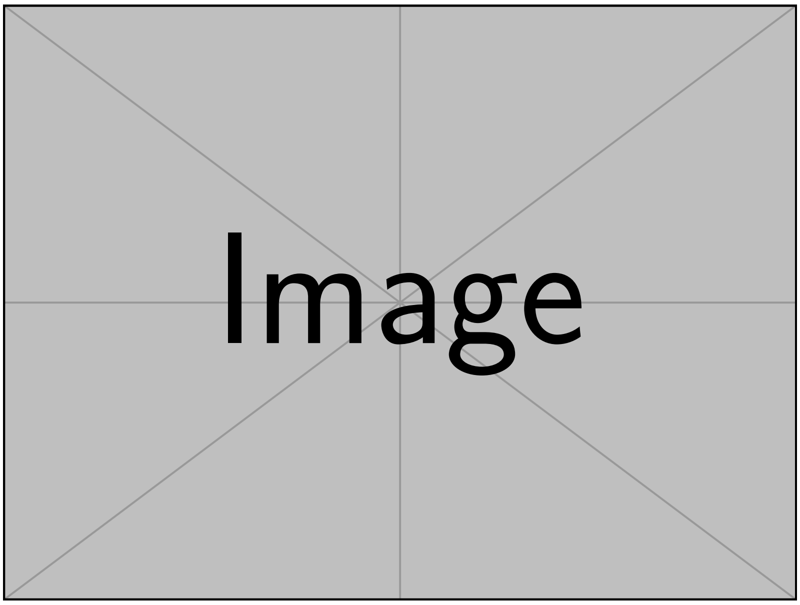

Figure 1.1: Sketch 1.01

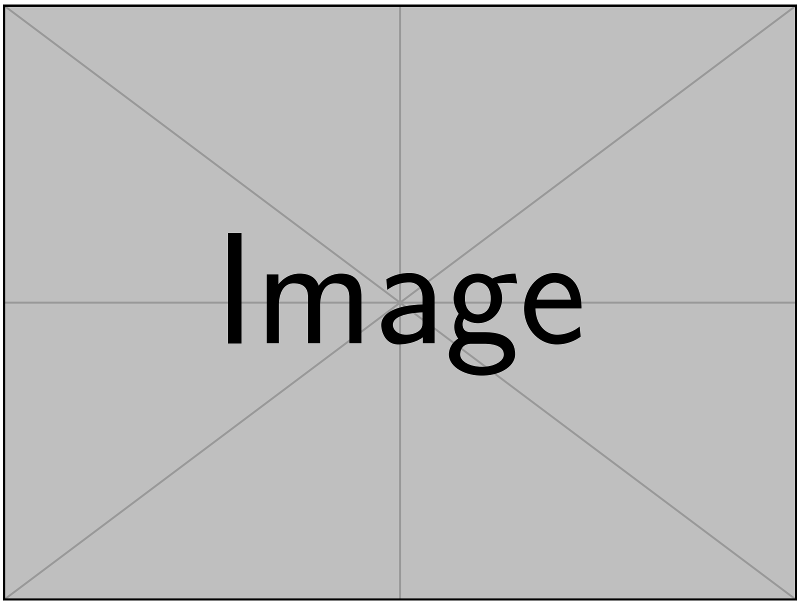

Figure 1.2: Sketch 1.02: Mountain car

Difference: In Reinforcement learning, we don't start with a model / ode.
Some part of reinforcement learning works model-free (i.e. assumes the model only implicitly)

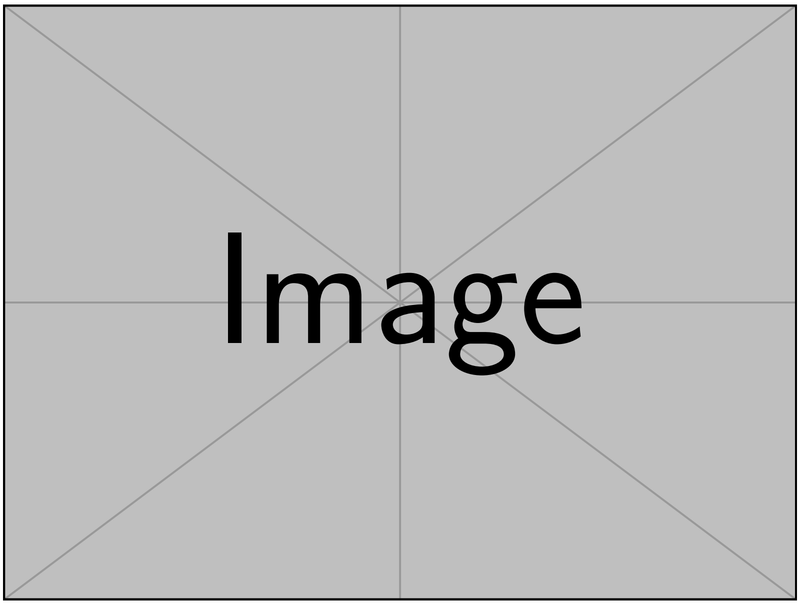

Figure 1.3: Sketch 1.03: cart pole / inverted pendulum

Next example: Acrobot (more then one equilibrium)

1.1 State Space Models

We have some

- **state space** $X, x \in X$
- **action space** $U, u \in U$
- **action** at step $k : u(k) \in U(k)$, i.e. we might have some constraints

- **observation space** $Y, y \in Y$

Definition 1.1. *Given state, action and observation spaces* X, U, Y*, a* ***state space model*** *is defined by*

$$x(k+1) = \mathcal{F}(x(k), u(k)) \tag{1}$$
$$y(k) = \mathcal{C}(x(k), u(k)) \tag{2}$$

$x(k)$ might include the past, might be useful for the stock trading problem

Remark. *Overcomplicating problems by loading lots of information into the state space, might make the problem harder!*

1.1.1 Linear State Space Model

$$x(k+1) = Fx(k) + Gu(k) \tag{3}$$
$$y(k) = Cx(k) + Du(k) \tag{4}$$

Remark. *The representations (in terms of the matrices) might not be unique!*

Common scenario for (3) is to keep $x(k)$ near the origin. You have to think about robustness of the system. Disturbances should be handled by the system.

$$u(k) = -Kx(k).$$

Consider a disturbance under the same control:

$$u(k) = -Kx(k) + v(k)$$

inserting this into (3) yields

$$\begin{aligned} x(k+1) &= (F - GK)x(k) - Gv(k) \\ y(k) &= (C - DK)x(k) + Dv(k) \end{aligned}$$

Closed vs open loop: In closed loops we don't change our course based on observations, while in open loop systems we do.

1.1.2 State Space Models in continuous Time

$$\frac{d}{dt}x = f(x, u)$$

for $x \in \mathbb{R}^n, u \in \mathbb{R}^m$. We often write u_t, x_t for u, x at time t. If f is linear we get

$$\begin{aligned} \frac{d}{dt}x &= Ax + Bu \\ y &= Cx + Du \end{aligned}$$

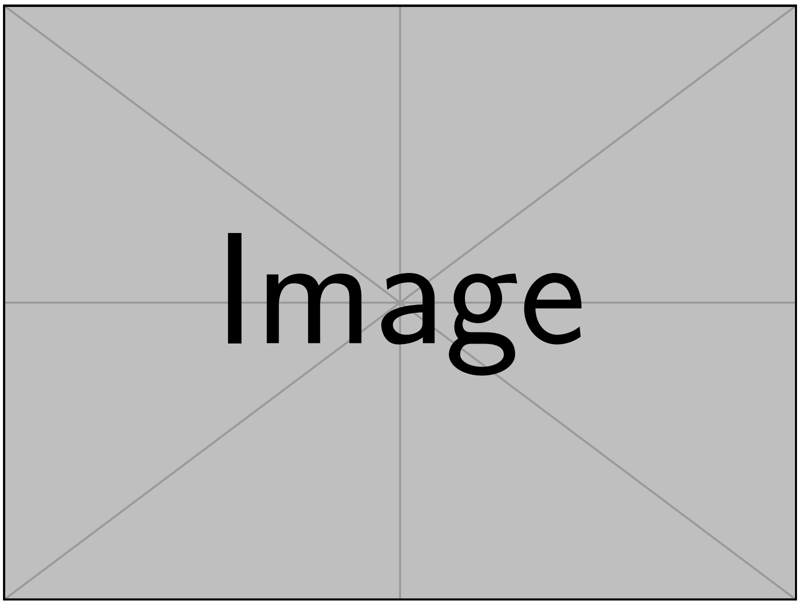

Figure 1.4: Sketch 1.04

To discretize we use the **forward Euler method**. Given time interval Δ

$$x(k+1) = x(k) + \Delta f(x(k), u(k))$$

so in (1) $\mathcal{F}(x,u) = x + \Delta f(x,u)$. Using Taylor

$$x_{t+\Delta} = x_t \Delta f(x,u) + O(\Delta^2)$$

For the linear model we get $F = I + \Delta A$

$$x(k+1) = x(k) + \Delta A x(k) + \underbrace{\Delta B}_{=:G} u(k)$$

For now fix some policy ϕ, so $u(k) = \phi(x(k))$:

$$x(k+1) = \mathcal{F}(x(k))$$

Assumption 1.2. *The state space X is equal to $\mathbb{R}^n$ or a closed subset of $\mathbb{R}^n$.*

Definition 1.3. *An **equilibrium** x^e is a state at which is system is frozen:*

$$x^e = \mathcal{F}(x^e).$$

Definition 1.4. *Given a **cost function** $C : X \to \mathbb{R}_+$ and a policy ϕ we define*

$$J_\phi(x) = J(x) = \sum_{k=0}^{\infty} C(x(k)),\ x(0) = x$$

*This is called **total cost** or **value function** of the policy ϕ.*

*The same concept with a different sign comes up in RL under the term **reward***

Given x^e, we usually assume $C(x^e) = 0$. Generally, we consider a discount factor γ^k in front of $C(x(k))$.

Definition 1.5. *Denote by $\mathcal{X}(k; x_0)$ the state step k with initial condition x_0 and following fixed policy ϕ. The equilibrium x^e is **stable in the sense of Lyapunov** if for all $\epsilon > 0 \exists \delta > 0$ s.t. $\|x_0 - x^e\| < \delta$, then*

$$\|\mathcal{X}(k; x_0) - \mathcal{X}(k; x^e)\| < \epsilon \forall k \geq 0$$

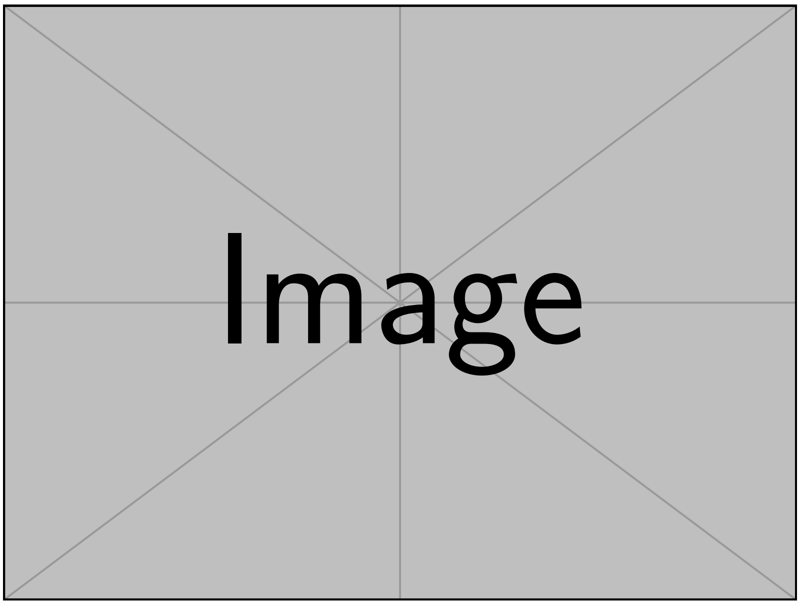

Figure 1.5: Sketch about Lyapunov stability

Definition 1.6. *An equilibrium is said to be* ***asymptotically stable*** *if x^e is stable in the sense of Lyapunov and for some $\delta_0 > 0$, whenever $\|x_0 - x^e\| < \delta_0$, it follows*

$$\lim_{k\to\infty} \mathcal{X}(k, x_0) = x^e.$$

The set of x_0 for which this holds is the ***region of attraction*** *for x^e, An equilibrium is* ***globally asymptotically stable*** *if the region of attraction is X.*

Start of lecture 02 (15.04.2025)

Definition 1.7 (Lyapunov function)**.** *A function $V : X \to \mathbb{R}_+$ is called* ***Lyapunov function****. We frequently assume V is* ***inf-compact****, i.e.: it holds*

$$\forall x^0 \in X: \ \{x \in X \mid V(x) \le V(x^0)\} \text{ is a bounded set.}$$

Remark. *There is some variability in the definition of Lyapunov functions! We often assume $V(x)$ is large if x is large.*

Sublevel sets:

$$S_V(r) = \{x \in X \mid V(x) \le r\}.$$

On can see with V being inf-compact $S_V(r)$ is either

- empty
- the whole domain X — We usually want to avoid this
- a bounded subset of X.

Usually, $S_V(r) = X$ is impossible, a common assumption is **coersiveness**:

$$\lim_{\|x\|\to\infty} V(x) = \infty.$$

Example.

- *$V(x) = x^2$, coercive*
- *$V(x) = \frac{x^2}{(1+x)^2}$, not coercive, but inf-compact $r > 1 : S_V(r) = \mathbb{R},\ r < 1 : S_V(r) = [-a, a]$ with $a = \sqrt{\frac{r}{1+r}}$*
- *$V(x) = e^x$ is neither*

Lemma 1.8. *Suppose that the cost function C and the value function J from definition 1.5 are non-negative and finite valued.*

this is a assumption on the value function

1. *$J(x(k))$ is non-increasing in k and $\lim_{k\to\infty} J(x(k)) = 0$ for each initial condition.*
2. *In addition let J be continuous, inf-compact and vanishing only at x^e. Then for each initial condition*
$$\lim_{k\to\infty} x(k) = x^e$$

Proof. Consider $J(x) = \sum_{k=0}^{\infty} c(x(k))$, then

$$\begin{aligned} J(x) &= c(x) + \sum_{k=1}^{\infty} c(x(k)) \\ &= c(x) + \sum_{k=0}^{\infty} c(x^+(k));\ x^+(0) = \mathcal{F}(x) \\ &= c(x) + J(\mathcal{F}(x)) \end{aligned}$$

This is the **dynamic programming principle** for a **fixed policy**. It is also called **Bellmann equation**. For 1. from this it follows

We are separating one step!
This is the same Bellman from the curse of dimensionality!

$$J(x(k+1)) + c(x) - J(x(k)) = 0$$

summing up from $k = 0$ up to $N - 1$

$$\begin{aligned} J(x) = J(x(N)) + \sum_{k=0}^{N-1} c(x(k)) \\ \implies \text{non-increasing} \end{aligned}$$

Taking the limit

$$= \lim_{N\to\infty} \left[J(x(N) + \sum_{k=0}^{N-1} c(x(k))) \right] = \left[\lim_{N\to\infty} J(x(N)) \right] + J(x)$$

using $J(x)$ is finite gives (i).
For 2. with $r = J(x)$, we get $x(k) \in S_J(k) \forall k$. Now suppose $\{x(k_i)\}$ is a convergent subsequence of the trajectory with limit x^∞. Then $J(x^\infty) = \lim_{i\to\infty} J(x(k_i)) = 0$ by the continuity of J. We assumed $J(x) = 0 \iff x^e = x \implies x^\infty = x^e$. Finally, the assumption follows, since each convergent subsequence reach the same value x^e.

□

Definition 1.9 (Poisson's inequality)**.** *Let $V, c : X \to \mathbb{R}_+$ and $\eta \geq 0$. Then* ***Poisson's inequality*** *states that*

We often assume $\eta = 0$

$$V(\mathcal{F}(x)) \leq V(x) - c(x) + \eta.$$

Proposition 1.10. *Suppose the Poisson inequality holds with $\eta = 0$. Additionally V shall be continuous, inf-compact and it shall have a unique minima at x^e. Then x^e is stable in the sense of Lyapunov (**sitsoL**).*

Proof.
$$\bigcap \{S_V(r) \mid r > V(x^e)\} = \{S_V(r)_{|_{r=V(x^e)}}\} \overset{\text{unique minimizer}}{=} \{x^e\}.$$

Using compactness we get: For each $\epsilon > 0$, we can find some $r > V(x^e)$ and some $\delta < \epsilon$ s.t.

$$\{x \in X \mid \|x - x^e\| < \delta\} \subset S_V(r) \subset \{x \in X \mid \|x - x^e\| < \epsilon\}$$

If $\|x_0 - x^e\| < \delta$, then $x_0 \in S_v(r)$ and hence $x(k) \in S_v(k)$ since $V(x(k))$ is non-increasing. With the second inclusion we see

$$\|\| - x^e\| < \epsilon \forall k$$

This gives sitsoL. □

Proposition 1.11 (Comparison theorem). *Poisson's inequality implies*

We don't write that explictlly, but we don't start in x^e!

1. *For each $N \geq 1$ and $x = x(0)$*

$$V(x(N)) + \sum_{k=0}^{N-1} c(x(k)) \leq V(x) + N\eta$$

2. *If $\eta = 0$, then $J(x) \leq V(x) \forall x$*

3. *Assume $\eta = 0$ and V, c are continuous. Suppose that c is inf-compact and vanishes only at the equilibrium x^e. Then x^e is globally asymptotically stable.*

Proof. 1.

$$V(x(k+1)) - V(x(k)) + c(x(k)) \leq \eta$$

summing up from 0 to $N-1$:

$$V(x(N)) - V(x(0)) + \sum_{k=0}^{N-1} c(x(k)) \leq N\eta$$

2. for $\eta = 0$the above is ≤ 0, so $\sum_{k=0}^{N-1} c(x(k)) \leq V(x(0)) - V(x(k)) \leq V(x(0))$ where the LHS converges to $J(x(0))$ for $N \to \infty$
3. Show sitsoL, with $\eta = 0$ it follows form proposition 1.9 that $V(x) \geq c(x)$, which gives V is also inf-compact. c is vanishing only at x^e, so $V(x(k))$ is strictly decreasing. When $x(k) \neq x^e$, implies $V(x(k)) \downarrow V(x^e)$ for each $x(0)$. Further

This is important!

$$V(x^e) < V(x(0)) \ \forall x(0) \in X \setminus \{x^e\}.$$

So it is a unique minimum. V has therefore the properties of proposition 1.10, which gives sitsoL. For global: with 1. we get

$$\lim_{k \to \infty} c(x(k)) = 0$$

and assumptions give us by lemma 1.8 that $x(k) \to x^e$ as $k \to \infty$. So, we converge from any initial condition, which gives global asymptotical stability.

□

Proposition 1.12. *Suppose that $V(\mathcal{F}(x)) = V(x) - c(x)$. Further, we assume that*

1. *J is continuous, inf-compact, vanishing only at x^e*

2. *V is continuous*

Then $J(x) = V(x) - V(x^e)$.

Proof. As before we sum up:

$$V(x(0)) + \overbrace{\sum_{k=0}^{N-1} c(x(k))}^{J(x(N-1)) \overset{N\to\infty}{\to} J(x)} = V(x).$$

Lemma 1.8 together with the continuity of V implies that

$$V(x(N)) \to V(x^e) \quad \text{as } N \to \infty.$$

This gives

$$V(x^e) + J(x) = V(x)$$
